DRAFT Inventory of U.S. Greenhouse Gas Emissions and Sinks:

1990 – 2015

FEBRUARY 15, 2017

U.S. Environmental Protection Agency
1200 Pennsylvania Ave., N.W.
Washington, DC 20460
U.S.A.

HOW TO OBTAIN COPIES

You can electronically download this document on the U.S. EPA's homepage at <http://www3.epa.gov/climatechange/emissions/usinventoryreport.html>.

All data tables of this document for the full time series 1990 through 2015, inclusive, will be made available for the final report published on April 15, 2017 at the internet site mentioned above.

FOR FURTHER INFORMATION

Contact Ms. Mausami Desai, Environmental Protection Agency, (202) 343-9381, desai.mausami@epa.gov.

Or Ms. Melissa Weitz, Environmental Protection Agency, (202) 343-9897, weitz.melissa@epa.gov.

For more information regarding climate change and greenhouse gas emissions, see the EPA web site at <https://www.epa.gov/climatechange>.

Acknowledgments

The Environmental Protection Agency would like to acknowledge the many individual and organizational contributors to this document, without whose efforts this report would not be complete. Although the complete list of researchers, government employees, and consultants who have provided technical and editorial support is too long to list here, EPA's Office of Atmospheric Programs would like to thank some key contributors and reviewers whose work has significantly improved this year's report.

Work on emissions from fuel combustion was led by Leif Hockstad and Vincent Camobreco. Amy Bunker, Sarah Froman, Susan Burke, and Sarah Roberts directed the work on mobile combustion and transportation. Work on industrial processes and product use emissions was led by Mausami Desai and John Steller. Work on fugitive methane emissions from the energy sector was directed by Melissa Weitz and Cate Hight. Calculations for the waste sector were led by Rachel Schmeltz. Tom Wirth directed work on the Agriculture and the Land Use, Land-Use Change, and Forestry chapters, with support from John Steller. Work on emissions of HFCs, PFCs, SF₆, and NF₃ was directed by Deborah Ottinger and Dave Godwin.

Within the EPA, other Offices also contributed data, analysis, and technical review for this report. The Office of Transportation and Air Quality and the Office of Air Quality Planning and Standards provided analysis and review for several of the source categories addressed in this report. The Office of Solid Waste and the Office of Research and Development also contributed analysis and research.

The Energy Information Administration and the Department of Energy contributed invaluable data and analysis on numerous energy-related topics. The U.S. Forest Service prepared the forest carbon inventory, and the Department of Agriculture's Agricultural Research Service and the Natural Resource Ecology Laboratory at Colorado State University contributed leading research on nitrous oxide and carbon fluxes from soils. The National Oceanic and Atmospheric Administration prepared the estimates of emissions from Coastal Wetlands.

Other government agencies have contributed data as well, including the U.S. Geological Survey, the Federal Highway Administration, the Department of Transportation, the Bureau of Transportation Statistics, the Department of Commerce, the National Agricultural Statistics Service, the Federal Aviation Administration, and the Department of Defense.

We would also like to thank Marian Martin Van Pelt and the full Inventory team at ICF including Leslie Chinery, Randy Freed, Diana Pape, Robert Lanza, Lauren Marti, Mollie Averyt, Mark Flugge, Larry O'Rourke, Deborah Harris, Jonathan Cohen, Alexander Lataille, Sabrina Andrews, Bikash Acharya, Claire Boland, Rebecca Ferenchiak, Kasey Knoell, Kevin Kurkul, Cory Jemison, Matt Lichtash, Jessica Kuna, Emily Kent, Emily Golla, Rani Murali, Drew Stilson, Cara Blumenthal, Tim Storer, Louise Huttering, and Jessica Klion for synthesizing this report and preparing many of the individual analyses.

Finally, we thank the following teams for their significant analytical support: Eastern Research Group team (Casey Pickering, Brandon Long, Clint Burklin, Gopi Manne, Deborah Bartram, Kara Edquist, Ami Aguiar and Brian Guzzone); RTI International (Kate Bronstein, Meaghan McGrath); Raven Ridge Resources, and Ruby Canyon Engineering Inc. (Michael Cote, Samantha Phillips, and Phillip Cunningham).

Preface

1
2 The United States Environmental Protection Agency (EPA) prepares the official U.S. Inventory of Greenhouse Gas
3 Emissions and Sinks to comply with existing commitments under the United Nations Framework Convention on
4 Climate Change (UNFCCC). Under decision 3/CP.5 of the UNFCCC Conference of the Parties, national inventories
5 for UNFCCC Annex I parties should be provided to the UNFCCC Secretariat each year by April 15.

6 In an effort to engage the public and researchers across the country, the EPA has instituted an annual public review
7 and comment process for this document. The availability of the draft document is announced via Federal Register
8 Notice and is posted on the EPA web site. Copies are also mailed upon request. The public comment period is
9 generally limited to 30 days; however, comments received after the closure of the public comment period are
10 accepted and considered for the next edition of this annual report.

Table of Contents

1			
2	TABLE OF CONTENTS		IV
3	LIST OF TABLES, FIGURES, AND BOXES		VII
4	EXECUTIVE SUMMARY		ES-1
5	ES.1 Background Information		ES-2
6	ES.2 Recent Trends in U.S. Greenhouse Gas Emissions and Sinks		ES-4
7	ES.3 Overview of Sector Emissions and Trends		ES-17
8	ES.4 Other Information		ES-22
9	1. INTRODUCTION		1-1
10	1.1 Background Information		1-3
11	1.2 National Inventory Arrangements		1-10
12	1.3 Inventory Process		1-13
13	1.4 Methodology and Data Sources.....		1-15
14	1.5 Key Categories		1-15
15	1.6 Quality Assurance and Quality Control (QA/QC).....		1-19
16	1.7 Uncertainty Analysis of Emission Estimates.....		1-20
17	1.8 Completeness		1-22
18	1.9 Organization of Report.....		1-22
19	2. TRENDS IN GREENHOUSE GAS EMISSIONS		2-1
20	2.1 Recent Trends in U.S. Greenhouse Gas Emissions and Sinks.....		2-1
21	2.2 Emissions by Economic Sector		2-22
22	2.3 Indirect Greenhouse Gas Emissions (CO, NO _x , NMVOCs, and SO ₂)		2-33
23	3. ENERGY		3-1
24	3.1 Fossil Fuel Combustion (IPCC Source Category 1A)		3-4
25	3.2 Carbon Emitted from Non-Energy Uses of Fossil Fuels (IPCC Source Category 1A)		3-41
26	3.3 Incineration of Waste (IPCC Source Category 1A1a).....		3-48
27	3.4 Coal Mining (IPCC Source Category 1B1a)		3-52
28	3.5 Abandoned Underground Coal Mines (IPCC Source Category 1B1a)		3-57
29	3.6 Petroleum Systems (IPCC Source Category 1B2a).....		3-61

1	3.7	Natural Gas Systems (IPCC Source Category 1B2b).....	3-71
2	3.8	Energy Sources of Indirect Greenhouse Gas Emissions.....	3-85
3	3.9	International Bunker Fuels (IPCC Source Category 1: Memo Items).....	3-86
4	3.10	Wood Biomass and Ethanol Consumption (IPCC Source Category 1A).....	3-91
5	4.	INDUSTRIAL PROCESSES AND PRODUCT USE.....	4-1
6	4.1	Cement Production (IPCC Source Category 2A1).....	4-7
7	4.2	Lime Production (IPCC Source Category 2A2).....	4-10
8	4.3	Glass Production (IPCC Source Category 2A3).....	4-15
9	4.4	Other Process Uses of Carbonates (IPCC Source Category 2A4).....	4-18
10	4.5	Ammonia Production (IPCC Source Category 2B1).....	4-21
11	4.6	Urea Consumption for Non-Agricultural Purposes.....	4-25
12	4.7	Nitric Acid Production (IPCC Source Category 2B2).....	4-28
13	4.8	Adipic Acid Production (IPCC Source Category 2B3).....	4-32
14	4.9	Silicon Carbide Production and Consumption (IPCC Source Category 2B5).....	4-35
15	4.10	Titanium Dioxide Production (IPCC Source Category 2B6).....	4-38
16	4.11	Soda Ash Production and Consumption (IPCC Source Category 2B7).....	4-41
17	4.12	Petrochemical Production (IPCC Source Category 2B8).....	4-44
18	4.13	HCFC-22 Production (IPCC Source Category 2B9a) – TO BE UPDATED FOR FINAL INVENTORY	
19	REPORT.....		4-50
20	4.14	Carbon Dioxide Consumption (IPCC Source Category 2B10).....	4-52
21	4.15	Phosphoric Acid Production (IPCC Source Category 2B10).....	4-56
22	4.16	Iron and Steel Production (IPCC Source Category 2C1) and Metallurgical Coke Production.....	4-59
23	4.17	Ferroalloy Production (IPCC Source Category 2C2).....	4-69
24	4.18	Aluminum Production (IPCC Source Category 2C3).....	4-72
25	4.19	Magnesium Production and Processing (IPCC Source Category 2C4).....	4-77
26	4.20	Lead Production (IPCC Source Category 2C5).....	4-82
27	4.21	Zinc Production (IPCC Source Category 2C6).....	4-85
28	4.22	Semiconductor Manufacture (IPCC Source Category 2E1).....	4-90
29	4.23	Substitution of Ozone Depleting Substances (IPCC Source Category 2F).....	4-101
30	4.24	Electrical Transmission and Distribution (IPCC Source Category 2G1).....	4-108
31	4.25	Nitrous Oxide from Product Uses (IPCC Source Category 2G3).....	4-115
32	4.26	Industrial Processes and Product Use Sources of Indirect Greenhouse Gases.....	4-118
33	5.	AGRICULTURE.....	5-1
34	5.1	Enteric Fermentation (IPCC Source Category 3A).....	5-2
35	5.2	Manure Management (IPCC Source Category 3B).....	5-8
36	5.3	Rice Cultivation (IPCC Source Category 3C).....	5-15
37	5.4	Agricultural Soil Management (IPCC Source Category 3D).....	5-20

1	5.5	Liming (IPCC Source Category 3G)	5-34
2	5.6	Urea Fertilization (IPCC Source Category 3H).....	5-37
3	5.7	Field Burning of Agricultural Residues (IPCC Source Category 3F)	5-39
4	6.	LAND USE, LAND-USE CHANGE, AND FORESTRY	6-1
5	6.1	Representation of the U.S. Land Base	6-7
6	6.2	Forest Land Remaining Forest Land	6-20
7	6.3	Land Converted to Forest Land (IPCC Source Category 4A2)	6-41
8	6.4	Cropland Remaining Cropland (IPCC Source Category 4B1)	6-47
9	6.5	Land Converted to Cropland (IPCC Source Category 4B2).....	6-56
10	6.6	Grassland Remaining Grassland (IPCC Source Category 4C1)	6-62
11	6.7	Land Converted to Grassland (IPCC Source Category 4C2)	6-71
12	6.8	Wetlands Remaining Wetlands (IPCC Source Category 4D1)	6-77
13	6.9	Land Converted to Wetlands (IPCC Source Category 4D2)	6-95
14	6.10	Settlements Remaining Settlements	6-98
15	6.11	Land Converted to Settlements (IPCC Source Category 3B5b).....	6-114
16	6.12	Other Land Remaining Other Land (IPCC Source Category 4F1).....	6-119
17	6.13	Land Converted to Other Land (IPCC Source Category 4F2).....	6-119
18	7.	WASTE.....	7-1
19	7.1	Landfills (IPCC Source Category 5A1).....	7-3
20	7.2	Wastewater Treatment (IPCC Source Category 5D).....	7-17
21	7.3	Composting (IPCC Source Category 5B1).....	7-32
22	7.4	Waste Incineration (IPCC Source Category 5C1).....	7-35
23	7.5	Waste Sources of Indirect Greenhouse Gases	7-35
24	8.	OTHER	8-1

Executive Summary

An emissions inventory that identifies and quantifies a country's primary anthropogenic¹ sources and sinks of greenhouse gases is essential for addressing climate change. This inventory adheres to both (1) a comprehensive and detailed set of methodologies for estimating sources and sinks of anthropogenic greenhouse gases, and (2) a common and consistent mechanism that enables Parties to the United Nations Framework Convention on Climate Change (UNFCCC) to compare the relative contribution of different emission sources and greenhouse gases to climate change.

In 1992, the United States signed and ratified the UNFCCC. As stated in Article 2 of the UNFCCC, “The ultimate objective of this Convention and any related legal instruments that the Conference of the Parties may adopt is to achieve, in accordance with the relevant provisions of the Convention, stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. Such a level should be achieved within a time-frame sufficient to allow ecosystems to adapt naturally to climate change, to ensure that food production is not threatened and to enable economic development to proceed in a sustainable manner.”²

Parties to the Convention, by ratifying, “shall develop, periodically update, publish and make available...national inventories of anthropogenic emissions by sources and removals by sinks of all greenhouse gases not controlled by the Montreal Protocol, using comparable methodologies...”³ The United States views this report as an opportunity to fulfill these commitments.

This chapter summarizes the latest information on U.S. anthropogenic greenhouse gas emission trends from 1990 through 2015. To ensure that the U.S. emissions inventory is comparable to those of other UNFCCC Parties, the estimates presented here were calculated using methodologies consistent with those recommended in the 2006 *Intergovernmental Panel on Climate Change (IPCC) Guidelines for National Greenhouse Gas Inventories* (IPCC 2006). The structure of this report is consistent with the UNFCCC guidelines for inventory reporting.⁴

Box ES-1: Methodological Approach for Estimating and Reporting U.S. Emissions and Sinks

In following the UNFCCC requirement under Article 4.1 to develop and submit national greenhouse gas emissions inventories, the gross emissions total presented in this report for the United States excludes emissions and sinks from LULUCF. The net emissions total presented in this report for the United States includes emissions and sinks from LULUCF. All emissions and sinks are calculated using internationally-accepted methods provided by the

¹ The term “anthropogenic,” in this context, refers to greenhouse gas emissions and removals that are a direct result of human activities or are the result of natural processes that have been affected by human activities (IPCC 2006).

² Article 2 of the Framework Convention on Climate Change published by the UNEP/WMO Information Unit on Climate Change. See <<http://unfccc.int>>.

³ Article 4(1)(a) of the United Nations Framework Convention on Climate Change (also identified in Article 12). Subsequent decisions by the Conference of the Parties elaborated the role of Annex I Parties in preparing national inventories. See <<http://unfccc.int>>.

⁴ See <<http://unfccc.int/resource/docs/2013/cop19/eng/10a03.pdf>>.

1 IPCC.⁵ Additionally, the calculated emissions and sinks in a given year for the United States are presented in a
2 common manner in line with the UNFCCC reporting guidelines for the reporting of inventories under this
3 international agreement.⁶ The use of consistent methods to calculate emissions and sinks by all nations providing
4 their inventories to the UNFCCC ensures that these reports are comparable. In this regard, U.S. emissions and sinks
5 reported in this Inventory report are comparable to emissions and sinks reported by other countries. The report itself
6 follows this standardized format, and provides an explanation of the IPCC methods used to calculate emissions and
7 sinks, and the manner in which those calculations are conducted.

8 On October 30, 2009, the U.S. Environmental Protection Agency (EPA) published a rule for the mandatory
9 reporting of greenhouse gases from large greenhouse gas emissions sources in the United States. Implementation of
10 40 CFR Part 98 is referred to as the Greenhouse Gas Reporting Program (GHGRP). 40 CFR part 98 applies to direct
11 greenhouse gas emitters, fossil fuel suppliers, industrial gas suppliers, and facilities that inject carbon dioxide (CO₂)
12 underground for sequestration or other reasons.⁷ Reporting is at the facility level, except for certain suppliers of
13 fossil fuels and industrial greenhouse gases. The GHGRP dataset and the data presented in this Inventory report are
14 complementary.

15 The GHGRP data set continues to be an important resource for the Inventory, providing not only annual emissions
16 information, but also other annual information, such as activity data and emissions factors that can improve and
17 refine national emission estimates and trends over time. GHGRP data also allow EPA to disaggregate national
18 inventory estimates in new ways that can highlight differences across regions and sub-categories of emissions, along
19 with enhancing application of QA/QC procedures and assessment of uncertainties.

20 EPA uses annual GHGRP data in a number of category estimates and continues to analyze the data on an annual
21 basis, as applicable, for further use to improve the national estimates presented in this Inventory consistent with
22 IPCC guidance.⁸

24 ES.1 Background Information

25 Greenhouse gases trap heat and make the planet warmer. The most important greenhouse gases directly emitted by
26 humans include carbon dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O), and several other fluorine-containing
27 halogenated substances. Although the direct greenhouse gases CO₂, CH₄, and N₂O occur naturally in the
28 atmosphere, human activities have changed their atmospheric concentrations. From the pre-industrial era (i.e.,
29 ending about 1750) to 2015, concentrations of these greenhouse gases have increased globally by 44, 162, and 21
30 percent, respectively (IPCC 2013 and NOAA/ESRL 2017). This annual report estimates the total national
31 greenhouse gas emissions and removals associated with human activities across the United States.

32 Global Warming Potentials

33 Gases in the atmosphere can contribute to climate change both directly and indirectly. Direct effects occur when the
34 gas itself absorbs radiation. Indirect radiative forcing occurs when chemical transformations of the substance
35 produce other greenhouse gases, when a gas influences the atmospheric lifetimes of other gases, and/or when a gas
36 affects atmospheric processes that alter the radiative balance of the earth (e.g., affect cloud formation or albedo).⁹

⁹ Albedo is a measure of the Earth's reflectivity, and is defined as the fraction of the total solar radiation incident on a body that is reflected by it.

1 The IPCC developed the Global Warming Potential (GWP) concept to compare the ability of each greenhouse gas to
2 trap heat in the atmosphere relative to another gas.

3 The GWP of a greenhouse gas is defined as the ratio of the accumulated radiative forcing within a specific time
4 horizon caused by emitting 1 kilogram of the gas, relative to that of the reference gas CO₂ (IPCC 2014). Direct
5 radiative effects occur when the gas itself is a greenhouse gas. The reference gas used is CO₂, and therefore GWP-
6 weighted emissions are measured in million metric tons of CO₂ equivalent (MMT CO₂ Eq.).^{10,11} All gases in this
7 Executive Summary are presented in units of MMT CO₂ Eq. Emissions by gas in unweighted mass tons are provided
8 in the Trends chapter of this report.

9 UNFCCC reporting guidelines for national inventories require the use of GWP values from the *IPCC Fourth*
10 *Assessment Report (AR4)* (IPCC 2007).¹² All estimates are provided throughout the report in both CO₂ equivalents
11 and unweighted units. A comparison of emission values using the AR4 GWP values versus the SAR (IPCC 1996),
12 and the *IPCC Fifth Assessment Report (AR5)* (IPCC 2013) GWP values can be found in Chapter 1 and, in more
13 detail, in Annex 6.1 of this report. The GWP values used in this report are listed below in Table ES-1.

14

15 **Table ES-1: Global Warming Potentials (100-Year Time Horizon) Used in this Report**

Gas	GWP

^a The CH₄ GWP includes the direct effects and those indirect effects due to the production of tropospheric ozone and stratospheric water vapor. The indirect effect due to production of CO₂ is not included.

16

17

¹⁰ Carbon comprises 12/44 of carbon dioxide by weight.

¹¹ One million metric ton is equal to 10¹² grams or one teragram.

¹² See <<http://unfccc.int/resource/docs/2013/cop19/eng/10a03.pdf>>.

ES.2 Recent Trends in U.S. Greenhouse Gas Emissions and Sinks

In 2015, total gross U.S. greenhouse gas emissions were 6,586.2 million metric tons (MMT) of CO₂ Eq. Total U.S. emissions have increased by 3.4 percent from 1990 to 2015, and emissions decreased from 2014 to 2015 by 2.2 percent (150.1 MMT CO₂ Eq.). The decrease in total greenhouse gas emissions between 2014 and 2015 was driven in large part by a decrease in CO₂ emissions from fossil fuel combustion. The decrease in CO₂ emissions from fossil fuel combustion was a result of multiple factors, including: (1) substitution from coal to natural gas consumption in the electric power sector; (2) warmer winter conditions in the first quarter of 2015 resulting in a decreased demand for heating fuel in the residential and commercial sectors; and (3) a slight decrease in electricity demand. Lastly, since 1990, U.S. emissions have increased at an average annual rate of 0.2 percent. Figure ES-1 through Figure ES-3 illustrate the overall trends in total U.S. emissions by gas, annual changes, and absolute change since 1990. Overall, net emissions in 2015 were 11.2 percent below 2005 levels as shown in Table ES-2.

Table ES-2 provides a detailed summary of gross U.S. greenhouse gas emissions and sinks for 1990 through 2015.

Figure ES-1: Gross U.S. Greenhouse Gas Emissions by Gas (MMT CO₂ Eq.)

Figure ES-2: Annual Percent Change in Gross U.S. Greenhouse Gas Emissions Relative to the Previous Year

Figure ES-3: Cumulative Change in Annual Gross U.S. Greenhouse Gas Emissions Relative to 1990 (1990=0, MMT CO₂ Eq.)

Table ES-2: Recent Trends in U.S. Greenhouse Gas Emissions and Sinks (MMT CO₂ Eq.)

Notes: Total emissions presented without LULUCF. Net emissions presented with LULUCF.

+ Does not exceed 0.05 MMT CO₂ Eq.

^a Emissions from Wood Biomass and Ethanol Consumption are not included specifically in summing Energy sector totals. Net carbon fluxes from changes in biogenic carbon reservoirs are accounted for in the estimates for Land Use, Land-Use Change, and Forestry.

^b Emissions from International Bunker Fuels are not included in totals.

^c Small amounts of PFC emissions also result from this source.

^d LULUCF emissions include the CO₂, CH₄, and N₂O emissions from *Peatlands Remaining Peatlands*; CH₄ and N₂O emissions reported for Non-CO₂ Emissions from Forest Fires, Non-CO₂ Emissions from Grassland Fires, and *Coastal Wetlands Remaining Coastal Wetlands*; CH₄ emissions from *Land Converted to Coastal Wetlands*; and N₂O Fluxes from Forest Soils and Settlement Soils.

^e LULUCF C Stock Change is the net C stock change from the following categories: *Forest Land Remaining Forest Land, Land Converted to Forest Land, Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, Land Converted to Grassland, Wetlands Remaining Wetlands, Land Converted to Wetlands, Settlements Remaining Settlements, and Land Converted to Settlements*. Refer to Table ES-5 for a breakout of emissions and removals for Land Use, Land-Use Change, and Forestry by gas and source category.

^f Quality control uncovered errors in the estimate and uncertainty of soil C stock changes for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, and Land Converted to Grassland* sections in the LULUCF chapter of this report.

^g The LULUCF Sector Net Total is the net sum of all emissions (i.e., sources) of greenhouse gases to the atmosphere plus removals of CO₂ (i.e., sinks or negative emissions) from the atmosphere.

Notes: Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

1 Figure ES-4 illustrates the relative contribution of the direct greenhouse gases to total U.S. emissions in 2015. Note,
 2 unless otherwise stated, all tables and figures provide total emissions without LULUCF. The primary greenhouse
 3 gas emitted by human activities in the United States was CO₂, representing approximately 82.2 percent of total
 4 greenhouse gas emissions. The largest source of CO₂, and of overall greenhouse gas emissions, was fossil fuel
 5 combustion. Methane emissions, which have decreased by 16.7 percent since 1990, resulted primarily from enteric
 6 fermentation associated with domestic livestock, natural gas systems, and decomposition of wastes in landfills.
 7 Agricultural soil management, manure management, mobile source fuel combustion and stationary fuel combustion
 8 were the major sources of N₂O emissions. Ozone depleting substance substitute emissions and emissions of HFC-23
 9 during the production of HCFC-22 were the primary contributors to aggregate hydrofluorocarbon (HFC) emissions.
 10 Perfluorocarbon (PFC) emissions resulted as a byproduct of primary aluminum production and from semiconductor
 11 manufacturing, electrical transmission and distribution systems accounted for most sulfur hexafluoride (SF₆)
 12 emissions, and semiconductor manufacturing is the only source of nitrogen trifluoride (NF₃) emissions.

13

14 **Figure ES-4: 2015 U.S. Greenhouse Gas Emissions by Gas (Percentages based on MMT CO₂**
 15 **Eq.)**

16

17

18 Overall, from 1990 to 2015, total emissions of CO₂ increased by 289.2 MMT CO₂ Eq. (5.6 percent), while total
 19 emissions of CH₄ decreased by 131.2 MMT CO₂ Eq. (16.7 percent), and N₂O emissions decreased by 24.5 MMT
 20 CO₂ Eq. (6.8 percent). During the same period, aggregate weighted emissions of HFCs, PFCs, SF₆ and NF₃ rose by
 21 85.9 MMT CO₂ Eq. (86.2 percent). From 1990 to 2015, HFCs increased by 127.5 MMT CO₂ Eq. (273.8 percent),
 22 PFCs decreased by 19.1 MMT CO₂ Eq. (78.7 percent), SF₆ decreased by 23.0 MMT CO₂ Eq. (79.8 percent), and
 23 NF₃ increased by 0.5 MMT CO₂ Eq. (1,057.0 percent). Despite being emitted in smaller quantities relative to the
 24 other principal greenhouse gases, emissions of HFCs, PFCs, SF₆ and NF₃ are significant because many of these
 25 gases have extremely high global warming potentials and, in the cases of PFCs and SF₆, long atmospheric lifetimes.
 26 Conversely, U.S. greenhouse gas emissions were partly offset by carbon (C) sequestration in forests, trees in urban
 27 areas, agricultural soils, landfilled yard trimmings and food scraps, and coastal wetlands, which, in aggregate, offset

1 5.9 percent of total emissions in 2015. The following sections describe each gas’s contribution to total U.S.
 2 greenhouse gas emissions in more detail.

3 Carbon Dioxide Emissions

4 The global carbon cycle is made up of large carbon flows and reservoirs. Billions of tons of carbon in the form of
 5 CO₂ are absorbed by oceans and living biomass (i.e., sinks) and are emitted to the atmosphere annually through
 6 natural processes (i.e., sources). When in equilibrium, carbon fluxes among these various reservoirs are roughly
 7 balanced.¹³ Since the Industrial Revolution (i.e., about 1750), global atmospheric concentrations of CO₂ have risen
 8 approximately 44 percent (IPCC 2013 and NOAA/ESRL 2017), principally due to the combustion of fossil fuels.
 9 Within the United States, fossil fuel combustion accounted for 93.3 percent of CO₂ emissions in 2015. Globally,
 10 approximately 32,381 MMT of CO₂ were added to the atmosphere through the combustion of fossil fuels in 2014, of
 11 which the United States accounted for approximately 16 percent.¹⁴ Changes in land use and forestry practices can
 12 lead to net CO₂ emissions (e.g., through conversion of forest land to agricultural or urban use) or to a net sink for
 13 CO₂ (e.g., through net additions to forest biomass). Although fossil fuel combustion is the greatest source of CO₂
 14 emissions, there are 24 additional sources included in the Inventory (Figure ES-5).

15 **Figure ES-5: 2015 Sources of CO₂ Emissions (MMT CO₂ Eq.)**

16
 17 Note: Fossil Fuel Combustion includes electricity generation, which also includes emissions of less than 0.05 MMT CO₂ Eq.
 18 from geothermal-based generation.

19 As the largest source of U.S. greenhouse gas emissions, CO₂ from fossil fuel combustion has accounted for
 20 approximately 77 percent of GWP-weighted emissions since 1990. The fundamental factors influencing emissions

¹³ The term “flux” is used to describe the net emissions of greenhouse gases accounting for both the emissions of CO₂ to and the removals of CO₂ from the atmosphere. Removal of CO₂ from the atmosphere is also referred to as “carbon sequestration.”

¹⁴ Global CO₂ emissions from fossil fuel combustion were taken from International Energy Agency *CO₂ Emissions from Fossil Fuels Combustion – Highlights* IEA (2016). See <<https://www.iea.org/publications/freepublications/publication/co2-emissions-from-fuel-combustion-highlights-2016.html>>.

1 levels include (1) changes in demand for energy and (2) a general decline in the carbon intensity of fuels combusted
 2 for energy in recent years by most sectors of the economy. Between 1990 and 2015, CO₂ emissions from fossil fuel
 3 combustion increased from 4,740.7 MMT CO₂ Eq. to 5,049.2 MMT CO₂ Eq., a 6.5 percent total increase over the
 4 twenty-six-year period. In addition, CO₂ emissions from fossil fuel combustion decreased from 2005 levels by 698.0
 5 MMT CO₂ Eq., a decrease of approximately 12.1 percent between 2005 to 2015. From 2014 to 2015, these
 6 emissions decreased by 153.0 MMT CO₂ Eq. (2.9 percent).

7 Historically, changes in emissions from fossil fuel combustion have been the dominant factor affecting U.S.
 8 emission trends. Changes in CO₂ emissions from fossil fuel combustion are influenced by many long-term and
 9 short-term factors. Long-term factors include population and economic trends, technological changes, shifting
 10 energy fuel choices, and various policies at the national, state, and local level. In the short term, the overall
 11 consumption of fossil fuels in the United States fluctuates primarily in response to changes in general economic
 12 conditions, energy prices, weather, and the availability of non-fossil alternatives.

13
 14 **Figure ES-6: 2015 CO₂ Emissions from Fossil Fuel Combustion by Sector and Fuel Type (MMT CO₂ Eq.)**
 15

16
 17
 18 **Figure ES-7: 2015 End-Use Sector Emissions of CO₂ from Fossil Fuel Combustion (MMT CO₂ Eq.)**
 19

20 The five major fuel consuming economic sectors contributing to CO₂ emissions from fossil fuel combustion are
 21 electricity generation, transportation, industrial, residential, and commercial. Carbon dioxide emissions are produced
 22 by the electricity generation sector as they consume fossil fuel to provide electricity to one of the other four sectors,
 23

1 or “end-use” sectors. For the discussion below, electricity generation emissions have been distributed to each end-
 2 use sector on the basis of each sector’s share of aggregate electricity consumption. This method of distributing
 3 emissions assumes that each end-use sector consumes electricity that is generated from the national average mix of
 4 fuels according to their carbon intensity. Emissions from electricity generation are also addressed separately after
 5 the end-use sectors have been discussed.

6 Note that emissions from U.S. Territories are calculated separately due to a lack of specific consumption data for the
 7 individual end-use sectors. Figure ES-6, Figure ES-7, and Table ES-3 summarize CO₂ emissions from fossil fuel
 8 combustion by end-use sector.

9 **Table ES-3: CO₂ Emissions from Fossil Fuel Combustion by End-Use Sector (MMT CO₂ Eq.)**

End-Use Sector	1990	2005	2011	2012	2013	2014	2015

Electricity	538.0	803.3	738.0	700.3	704.5	706.0	663.1
U.S. Territories^a	27.9	49.9	41.5	43.6	43.5	41.2	41.2
Total	4,740.7	5,747.1	5,227.7	5,024.7	5,157.6	5,202.1	5,049.2
Electricity Generation	1,820.8	2,400.9	2,157.7	2,022.2	2,038.1	2,038.0	1,900.7

^a Fuel consumption by U.S. Territories (i.e., American Samoa, Guam, Puerto Rico, U.S. Virgin Islands, Wake Island, and other U.S. Pacific Islands) is included in this report.

Notes: Combustion-related emissions from electricity generation are allocated based on aggregate national electricity consumption by each end-use sector. Totals may not sum due to independent rounding.

10 *Transportation End-Use Sector.* When electricity-related emissions are distributed to economic end-use sectors,
 11 transportation activities accounted for 34.4 percent of U.S. CO₂ emissions from fossil fuel combustion in 2015. The
 12 largest sources of transportation CO₂ emissions in 2015 were passenger cars (41.9 percent), medium- and heavy-
 13 duty trucks (23.6 percent), light-duty trucks, which include sport utility vehicles, pickup trucks, and minivans (17.5
 14 percent), commercial aircraft (6.9 percent), rail (2.5 percent), other aircraft (2.3 percent), pipelines (2.2 percent), and
 15 ships and boats (1.8 percent). Annex 3.2 presents the total emissions from all transportation and mobile sources,
 16 including CO₂, CH₄, N₂O, and HFCs.

17 In terms of the overall trend, from 1990 to 2015, total transportation CO₂ emissions rose by 16 percent due, in large
 18 part, to increased demand for travel. The number of VMT by light-duty motor vehicles (i.e., passenger cars and
 19 light-duty trucks) increased 42 percent from 1990 to 2015, as a result of a confluence of factors including population
 20 growth, economic growth, urban sprawl, and low fuel prices during the beginning of this period. Almost all of the
 21 energy consumed for transportation was supplied by petroleum-based products, with more than half being related to
 22 gasoline consumption in automobiles and other highway vehicles. Other fuel uses, especially diesel fuel for freight
 23 trucks and jet fuel for aircraft, accounted for the remainder.

24 *Industrial End-Use Sector.* Industrial CO₂ emissions, resulting both directly from the combustion of fossil fuels and
 25 indirectly from the generation of electricity that is consumed by industry, accounted for 27 percent of CO₂ from
 26 fossil fuel combustion in 2015. Approximately 60 percent of these emissions resulted from direct fossil fuel
 27 combustion to produce steam and/or heat for industrial processes. The remaining emissions resulted from consuming
 28 electricity for motors, electric furnaces, ovens, lighting, and other applications. In contrast to the other end-use
 29 sectors, emissions from industry have declined since 1990. This decline is due to structural changes in the U.S.

1 economy (i.e., shifts from a manufacturing-based to a service-based economy), fuel switching, and efficiency
2 improvements.

3 *Residential and Commercial End-Use Sectors.* The residential and commercial end-use sectors accounted for 20 and
4 18 percent, respectively, of CO₂ emissions from fossil fuel combustion in 2015. Both sectors relied heavily on
5 electricity for meeting energy demands, with 68 and 75 percent, respectively, of their emissions attributable to
6 electricity consumption for lighting, heating, cooling, and operating appliances. The remaining emissions were due
7 to the consumption of natural gas and petroleum for heating and cooking. Emissions from the residential and
8 commercial end-use sectors have increased by 8 percent and 18 percent since 1990, respectively.

9 *Electricity Generation.* The United States relies on electricity to meet a significant portion of its energy demands.
10 Electricity generators consumed 34 percent of total U.S. energy uses from fossil fuels and emitted 38 percent of the
11 CO₂ from fossil fuel combustion in 2015. The type of energy source used to generate electricity is the main factor
12 influencing emissions. For example, some electricity is generated through non-fossil fuel options such as nuclear,
13 hydroelectric, or geothermal energy. Including all electricity generation modes, electricity generators relied on coal
14 for approximately 33 percent of their total energy requirements in 2015.¹⁵ In addition, the coal used by electricity
15 generators accounted for 93 percent of all coal consumed for energy in the United States in 2015.¹⁶ Recently, a
16 decrease in the carbon intensity of fuels consumed to generate electricity has occurred due to a decrease in coal
17 consumption, and increased natural gas consumption and other generation sources. Including all electricity
18 generation modes, electricity generators used natural gas for approximately 33 percent of their total energy
19 requirements in 2015.¹⁷ Across the time series, changes in electricity demand and the carbon intensity of fuels used
20 for electricity generation have a significant impact on CO₂ emissions. While emissions from the electric power
21 sector have increased by approximately 4 percent since 1990, the carbon intensity of the electric power sector, in
22 terms of CO₂ Eq. per QBTu has significantly decreased by 16 percent during that same timeframe.

23 Other significant CO₂ trends included the following:

- 24 • Carbon dioxide emissions from non-energy use of fossil fuels increased by 9.4 MMT CO₂ Eq. (8.0 percent)
25 from 1990 through 2015. Emissions from non-energy uses of fossil fuels were 127.0 MMT CO₂ Eq. in
26 2015, which constituted 2.3 percent of total national CO₂ emissions, approximately the same proportion as
27 in 1990.
- 28 • Carbon dioxide emissions from iron and steel production and metallurgical coke production have decreased
29 by 51.8 MMT CO₂ Eq. (51.9 percent) from 1990 through 2015, due to restructuring of the industry,
30 technological improvements, and increased scrap steel utilization.
- 31 • Carbon dioxide emissions from ammonia production (10.8 MMT CO₂ Eq. in 2015) decreased by 2.2 MMT
32 CO₂ Eq. (17.2 percent) since 1990. Ammonia production relies on natural gas as both a feedstock and a
33 fuel, and as such, market fluctuations and volatility in natural gas prices affect the production of ammonia.
- 34 • Total C sequestration (i.e., net CO₂ removals) in the LULUCF sector decreased by approximately 16.0
35 percent between 1990 and 2015. This decrease was primarily due to a decrease in the rate of net C
36 accumulation in forest C stocks and an increase in emissions from *Land Converted to Grassland*.

37 **Box ES-2: Use of Ambient Measurements Systems for Validation of Emission Inventories**

38 In following the UNFCCC requirement under Article 4.1 to develop and submit national greenhouse gas emission
39 inventories, the emissions and sinks presented in this report are organized by source and sink categories and
40 calculated using internationally-accepted methods provided by the IPCC.¹⁸ Several recent studies have measured
41 emissions at the national or regional level with results that sometimes differ from EPA's estimate of emissions. EPA
42 has engaged with researchers on how remote sensing, ambient measurement, and inverse modeling techniques for
43 greenhouse gas emissions could assist in improving the understanding of inventory estimates. In working with the

¹⁵ See <http://www.eia.gov/energyexplained/index.cfm?page=electricity_in_the_united_states>.

¹⁶ See Table 6.2 Coal Consumption by Sector of EIA 2016.

¹⁷ See <http://www.eia.gov/energyexplained/index.cfm?page=electricity_in_the_united_states>.

¹⁸ See <<http://www.ipcc-nggip.iges.or.jp/public/index.html>>.

1 research community on ambient measurement and remote sensing techniques to improve national greenhouse gas
 2 inventories, EPA relies upon guidance from the IPCC on the use of measurements and modeling to validate
 3 emission inventories.¹⁹ An area of particular interest in EPA’s outreach efforts is how ambient measurement data can
 4 be used in a manner consistent with this Inventory report’s transparency on its calculation methodologies, and the
 5 ability of these techniques to attribute emissions and removals from remote sensing to anthropogenic sources, as
 6 defined by the IPCC for this report, versus natural sources and sinks.

7 In an effort to improve the ability to compare the national-level greenhouse gas inventory with measurement results
 8 that may be at other scales, a team at Harvard University along with EPA and other coauthors developed a gridded
 9 inventory of U.S. anthropogenic methane emissions with 0.1° x 0.1° spatial resolution, monthly temporal resolution,
 10 and detailed scale-dependent error characterization. The Inventory is designed to be consistent with the 1990 to 2014
 11 U.S. EPA *Inventory of U.S. Greenhouse Gas Emissions and Sinks* estimates for the year 2012, which presents
 12 national totals for different source types.²⁰

14 Methane Emissions

15 Methane (CH₄) is 25 times as effective as CO₂ at trapping heat in the atmosphere (IPCC 2007). Over the last two
 16 hundred and fifty years, the concentration of CH₄ in the atmosphere increased by 162 percent (IPCC 2013 and
 17 CDIAC 2016). Anthropogenic sources of CH₄ include natural gas and petroleum systems, agricultural activities,
 18 landfills, coal mining, wastewater treatment, stationary and mobile combustion, and certain industrial processes (see
 19 Figure ES-8).

21 **Figure ES-8: 2015 Sources of CH₄ Emissions (MMT CO₂ Eq.)**

24 Some significant trends in U.S. emissions of CH₄ include the following:

¹⁹ See <http://www.ipcc-nggip.iges.or.jp/meeting/pdfiles/1003_Uncertainty%20meeting_report.pdf>.

²⁰ See <<https://www.epa.gov/ghgemissions/gridded-2012-methane-emissions>>.

- 1 • Enteric fermentation is the largest anthropogenic source of CH₄ emissions in the United States. In 2015,
2 enteric fermentation CH₄ emissions were 166.5 MMT CO₂ Eq. (25.4 percent of total CH₄ emissions),
3 which represents an increase of 2.4 MMT CO₂ Eq. (1.5 percent) since 1990. This increase in emissions
4 from 1990 to 2015 generally follows the increasing trends in cattle populations. From 1990 to 1995,
5 emissions increased and then generally decreased from 1996 to 2004, mainly due to fluctuations in beef
6 cattle populations and increased digestibility of feed for feedlot cattle. Emissions increased from 2005 to
7 2007, as both dairy and beef populations increased. Research indicates that the feed digestibility of dairy
8 cow diets decreased during this period. Emissions decreased again from 2008 to 2015 as beef cattle
9 populations again decreased.
- 10 • Natural gas systems were the second largest anthropogenic source category of CH₄ emissions in the United
11 States in 2015 with 160.0 MMT CO₂ Eq. of CH₄ emitted into the atmosphere. Those emissions have
12 decreased by 36.5 MMT CO₂ Eq. (18.6 percent) since 1990. The decrease in CH₄ emissions is largely due
13 to the decrease in emissions from transmission, storage, and distribution. The decrease in transmission and
14 storage emissions is largely due to reduced compressor station emissions (including emissions from
15 compressors and fugitives). The decrease in distribution emissions is largely attributed to increased use of
16 plastic piping, which has lower emissions than other pipe materials, and station upgrades at metering and
17 regulating (M&R) stations.
- 18 • Landfills are the third largest anthropogenic source of CH₄ emissions in the United States (115.7 MMT
19 CO₂ Eq.), accounting for 17.7 percent of total CH₄ emissions in 2015. From 1990 to 2015, CH₄ emissions
20 from landfills decreased by 63.8 MMT CO₂ Eq. (35.6 percent), with small increases occurring in some
21 interim years. This downward trend in emissions coincided with increased landfill gas collection and
22 control systems, and a reduction of decomposable materials (i.e., paper and paperboard, food scraps, and
23 yard trimmings) discarded in MSW landfills over the time series,²¹ which has more than offset the
24 additional CH₄ emissions resulting from an increase in the amount of municipal solid waste landfilled.
- 25 • Methane emissions from manure management, the fourth largest anthropogenic source of CH₄ emissions in
26 the United States, increased by 78.3 percent since 1990, from 37.2 MMT CO₂ Eq. in 1990 to 66.3 MMT
27 CO₂ Eq. in 2015. The majority of this increase was from swine and dairy cow manure, since the general
28 trend in manure management is one of increasing use of liquid systems, which tends to produce greater
29 CH₄ emissions. The increase in liquid systems is the combined result of a shift to larger facilities, and to
30 facilities in the West and Southwest, all of which tend to use liquid systems. Also, new regulations limiting
31 the application of manure nutrients have shifted manure management practices at smaller dairies from daily
32 spread to manure managed and stored on site.
- 33 • Methane emissions from petroleum systems in the United States (41.5 MMT CO₂ Eq.) accounted for 6.3
34 percent of total CH₄ emissions in 2015. From 1990 to 2015, CH₄ emissions from petroleum systems
35 decreased by 16.8 MMT CO₂ Eq. (or 28.8 percent). Production segment CH₄ emissions have decreased by
36 around 8 percent from 2014 levels, primarily due to decreases in emissions from associated gas venting and
37 flaring.

38 Nitrous Oxide Emissions

39 Nitrous oxide (N₂O) is produced by biological processes that occur in soil and water and by a variety of
40 anthropogenic activities in the agricultural, energy-related, industrial, and waste management fields. While total N₂O
41 emissions are much lower than CO₂ emissions, N₂O is approximately 300 times more powerful than CO₂ at trapping
42 heat in the atmosphere (IPCC 2007). Since 1750, the global atmospheric concentration of N₂O has risen by
43 approximately 21 percent (IPCC 2013 and CDIAC 2016). The main anthropogenic activities producing N₂O in the
44 United States are agricultural soil management, stationary fuel combustion, fuel combustion in motor vehicles,
45 manure management, and nitric acid production (see Figure ES-9).

²¹ Carbon dioxide emissions from landfills are not included specifically in summing waste sector totals. Net carbon fluxes from changes in biogenic carbon reservoirs and disposed wood products are accounted for in the estimates for LULUCF.

1 **Figure ES-9: 2015 Sources of N₂O Emissions (MMT CO₂ Eq.)**

2
3

4 Some significant trends in U.S. emissions of N₂O include the following:

- 5 • Agricultural soils accounted for approximately 75.0 percent of N₂O emissions and 3.8 percent of total
6 emissions in the United States in 2015. Estimated emissions from this source in 2015 were 251.3 MMT
7 CO₂ Eq. Annual N₂O emissions from agricultural soils fluctuated between 1990 and 2015, although overall
8 emissions were 2.0 percent lower in 2015 than in 1990. Year-to-year fluctuations are largely a reflection of
9 annual variation in weather patterns, synthetic fertilizer use, and crop production.
- 10 • Nitrous oxide emissions from stationary combustion increased 11.2 MMT CO₂ Eq. (94.0 percent) from
11 1990 through 2015. Nitrous oxide emissions from this source increased primarily as a result of an increase
12 in the number of coal fluidized bed boilers in the electric power sector.
- 13 • In 2015, total N₂O emissions from manure management were estimated to be 17.7 MMT CO₂ Eq.;
14 emissions were 14.0 MMT CO₂ Eq. in 1990. These values include both direct and indirect N₂O emissions
15 from manure management. Nitrous oxide emissions have remained fairly steady since 1990. Small changes
16 in N₂O emissions from individual animal groups exhibit the same trends as the animal group populations,
17 with the overall net effect that N₂O emissions showed a 26.6 percent increase from 1990 to 2015 and a 1.1
18 percent increase from 2014 through 2015.
- 19 • Nitrous oxide emissions from mobile combustion decreased by 25.8 MMT CO₂ Eq. (62.7 percent) from
20 1990 through 2015, primarily as a result of N₂O national emission control standards and emission control
21 technologies for on-road vehicles.
- 22 • Nitrous oxide emissions from adipic acid production were 4.3 MMT CO₂ Eq. in 2015, and have decreased
23 significantly since 1990 due to both the widespread installation of pollution control measures in the late
24 1990s and plant idling in the late 2000s. Emissions from adipic acid production have decreased by 72.0
25 percent since 1990 and by 74.8 percent since a peak in 1995.

26 HFC, PFC, SF₆, and NF₃ Emissions

27 Hydrofluorocarbons (HFCs) and perfluorocarbons (PFCs) are families of synthetic chemicals that are used as
28 alternatives to ozone depleting substances (ODS), which are being phased out under the Montreal Protocol and
29 Clean Air Act Amendments of 1990. Hydrofluorocarbons and PFCs do not deplete the stratospheric ozone layer,
30 and are therefore acceptable alternatives under the Montreal Protocol on Substances that Deplete the Ozone Layer.

31 These compounds, however, along with SF₆ and NF₃, are potent greenhouse gases. In addition to having high global
32 warming potentials, SF₆ and PFCs have extremely long atmospheric lifetimes, resulting in their essentially

1 irreversible accumulation in the atmosphere once emitted. Sulfur hexafluoride is the most potent greenhouse gas the
2 IPCC has evaluated (IPCC 2013).

3 Other emissive sources of these gases include HCFC-22 production, electrical transmission and distribution systems,
4 semiconductor manufacturing, aluminum production, and magnesium production and processing (see Figure ES-10).

5

6 **Figure ES-10: 2015 Sources of HFCs, PFCs, SF₆, and NF₃ Emissions (MMT CO₂ Eq.)**

7
8

9

10

11 Some significant trends in U.S. HFC, PFC, SF₆, and NF₃ emissions include the following:

12 • Emissions resulting from the substitution of ODS (e.g., chlorofluorocarbons [CFCs]) have been
13 consistently increasing, from small amounts in 1990 to 168.6 MMT CO₂ Eq. in 2015. This increase was in
14 large part the result of efforts to phase out CFCs and other ODS in the United States. In the short term, this
15 trend is expected to continue, and will likely continue over the next decade as hydrochlorofluorocarbons
16 (HCFCs), which are interim substitutes in many applications, are themselves phased out under the
17 provisions of the Copenhagen Amendments to the Montreal Protocol.

18 • GWP-weighted PFC, HFC, SF₆, and NF₃ emissions from semiconductor manufacture have increased by
19 34.3 percent from 1990 to 2015, due to industrial growth and the adoption of emission reduction
20 technologies. Within that time span, emissions peaked in 1999, the initial year of EPA's PFC
21 Reduction/Climate Partnership for the Semiconductor Industry, but have since declined to 4.8 MMT CO₂
22 Eq. in 2015 (a 47.1 percent decrease relative to 1999).

23 • Sulfur hexafluoride emissions from electric power transmission and distribution systems decreased by 82.0
24 percent (19.0 MMT CO₂ Eq.) from 1990 to 2015. There are two potential causes for this decrease: (1) a
25 sharp increase in the price of SF₆ during the 1990s and (2) a growing awareness of the environmental
26 impact of SF₆ emissions through programs such as EPA's SF₆ Emission Reduction Partnership for Electric
27 Power Systems.

28 • Perfluorocarbon emissions from aluminum production decreased by 90.7 percent (19.5 MMT CO₂ Eq.)
29 from 1990 to 2015. This decline is due both to reductions in domestic aluminum production and to actions
30 taken by aluminum smelting companies to reduce the frequency and duration of anode effects.

ES.3 Overview of Sector Emissions and Trends

In accordance with the UNFCCC decision to set the 2006 IPCC Guidelines for National Greenhouse Gas Inventories (IPCC 2006) as the standard for Annex I countries at the Nineteenth Conference of the Parties (UNFCCC 2014), Figure ES-11 and Table ES-4 aggregate emissions and sinks by the sectors defined by those guidelines. Over the twenty-six-year period of 1990 to 2015, total emissions in the Energy, Industrial Processes and Product Use, and Agriculture grew by 215.7 MMT CO₂ Eq. (4.0 percent), 36.7 MMT CO₂ Eq. (10.9 percent), and 27.0 MMT CO₂ Eq. (5.5 percent), respectively. Over the same period, total emissions in the Waste sector decreased by 59.9 MMT CO₂ Eq. (30.1 percent) and estimates of net C sequestration in the Land Use, Land-Use Change, and Forestry (LULUCF) sector (magnitude of emissions plus CO₂ removals from all LULUCF source categories) decreased by 82.7 MMT CO₂ Eq. (18.4 percent).

Figure ES-11: U.S. Greenhouse Gas Emissions and Sinks by Chapter/IPCC Sector (MMT CO₂ Eq.)

Table ES-4: Recent Trends in U.S. Greenhouse Gas Emissions and Sinks by Chapter/IPCC Sector (MMT CO₂ Eq.)

Chapter/IPCC Sector	1990	2005	2011	2012	2013	2014	2015
Energy	5,333.8	6,279.4	5,721.8	5,506.9	5,659.3	5,703.2	5,549.4

Energy

The Energy chapter contains emissions of all greenhouse gases resulting from stationary and mobile energy activities including fuel combustion and fugitive fuel emissions, and the use of fossil fuels for non-energy purposes. Energy-related activities, primarily fossil fuel combustion, accounted for the vast majority of U.S. CO₂ emissions for the period of 1990 through 2015. In 2015, approximately 82 percent of the energy consumed in the United States (on a Btu basis) was produced through the combustion of fossil fuels. The remaining 18 percent came from other energy sources such as hydropower, biomass, nuclear, wind, and solar energy (see Figure ES-12). Energy-related activities are also responsible for CH₄ and N₂O emissions (42 percent and 12 percent of total U.S. emissions of each gas, respectively). Overall, emission sources in the Energy chapter account for a combined 84.3 percent of total U.S. greenhouse gas emissions in 2015.

Figure ES-12: 2015 U.S. Energy Consumption by Energy Source (Percent)

Industrial Processes and Product Use

The Industrial Processes and Product Use (IPPU) chapter includes greenhouse gas emissions occurring from industrial processes and from the use of greenhouse gases in products.

Greenhouse gas emissions are produced as the by-products of many non-energy-related industrial activities. For example, industrial processes can chemically transform raw materials, which often release waste gases such as CO₂, CH₄, and N₂O. These processes include iron and steel production and metallurgical coke production, cement production, ammonia production, urea consumption, lime production, other process uses of carbonates (e.g., flux stone, flue gas desulfurization, and glass manufacturing), soda ash production and consumption, titanium dioxide production, phosphoric acid production, ferroalloy production, CO₂ consumption, silicon carbide production and consumption, aluminum production, petrochemical production, nitric acid production, adipic acid production, lead production, zinc production, and N₂O from product uses. Industrial processes also release HFCs, PFCs, SF₆, and NF₃ and other fluorinated compounds. In addition to the use of HFCs and some PFCs as ODS substitutes, HFCs, PFCs, SF₆, NF₃, and other fluorinated compounds are employed and emitted by a number of other industrial sources in the United States. These industries include aluminum production, HCFC-22 production, semiconductor manufacture, electric power transmission and distribution, and magnesium metal production and processing. Overall, emission sources in the Industrial Process and Product Use chapter account for 5.7 percent of U.S. greenhouse gas emissions in 2015.

1 Agriculture

2 The Agriculture chapter contains anthropogenic emissions from agricultural activities (except fuel combustion,
3 which is addressed in the Energy chapter, and agricultural CO₂ fluxes, which are addressed in the Land Use, Land-
4 Use Change, and Forestry chapter). Agricultural activities contribute directly to emissions of greenhouse gases
5 through a variety of processes, including the following source categories: enteric fermentation in domestic livestock,
6 livestock manure management, rice cultivation, agricultural soil management, liming, urea fertilization, and field
7 burning of agricultural residues. CO₂, CH₄ and N₂O were the primary greenhouse gases emitted by agricultural
8 activities. CO₂ emissions from the application of crushed limestone and dolomite (i.e., soil liming) and urea
9 fertilization represented 0.2 percent of total CO₂ emissions from anthropogenic activities. CH₄ emissions from
10 enteric fermentation and manure management represented 25.4 percent and 10.1 percent of total CH₄ emissions from
11 anthropogenic activities, respectively, in 2015. Agricultural soil management activities such as fertilizer application
12 and other cropping practices were the largest source of U.S. N₂O emissions in 2015, accounting for 75.0 percent. In
13 2015, emission sources accounted for in the Agricultural chapters were responsible for 7.9 percent of total U.S.
14 greenhouse gas emissions.

15 Land Use, Land-Use Change, and Forestry

16 The Land Use, Land-Use Change, and Forestry chapter contains emissions of CH₄ and N₂O, and emissions and
17 removals of CO₂ from managed lands in the United States. Overall, managed land is a net sink for CO₂ (C
18 sequestration) in the United States. The drivers of fluxes on managed lands include, for example, forest management
19 practices, tree planting in urban areas, the management of agricultural soils, the landfilling of yard trimmings and
20 food scraps, and activities that cause changes in C stocks in coastal wetlands. The main drivers for net forest
21 sequestration include net forest growth and increasing forest area, as well as a net accumulation of C stocks in
22 harvested wood pools. The net sequestration in *Settlements Remaining Settlements*, which occurs predominantly
23 from urban forests and landfilled yard trimmings and food scraps, is a result of net tree growth and increased urban
24 forest size, as well as long-term accumulation of yard trimmings and food scraps carbon in landfills.

25 *Forest Land Remaining Forest Land* (including vegetation, soils, and harvested wood) represented the largest
26 carbon sink from LULUCF, accounting for 77 percent of total 2015 negative C fluxes; *Settlements Remaining*
27 *Settlements* (urban trees and landfilled yard trimmings and food scraps) accounted for 12 percent; *Land Converted to*
28 *Forest Land* accounted for 9 percent; and *Cropland Remaining Cropland*, *Wetlands Remaining Wetlands*, and *Land*
29 *Converted to Wetlands* accounted for 3 percent of the total negative C fluxes in 2015. Conversely, *Land Converted*
30 *to Grassland* represented the largest carbon source from LULUCF, accounting for 61 percent of total 2015 positive
31 C fluxes, while *Land Converted to Settlements* accounted for 31 percent. *Land Converted to Cropland* accounted for
32 6 percent. *Grassland Remaining Grassland* accounted for 2 percent, and settlement soils in *Settlements Remaining*
33 *Settlements* accounted for less than 0.5 percent of the total positive C fluxes in 2015. Overall, positive C fluxes
34 totaled 481.6 MMT CO₂ Eq. in 2015, while negative C fluxes totaled 868.5 MMT CO₂ Eq. in 2015.

35 The LULUCF sector in 2015 resulted in a net increase in C stocks (i.e., net CO₂ removals) of 386.8 MMT CO₂ Eq.
36 (Table ES-5).²² This represents an offset of 5.9 percent of total (i.e., gross) greenhouse gas emissions in 2015.
37 Emissions from LULUCF activities in 2015 are 20.4 MMT CO₂ Eq. and represent 0.3 percent of total greenhouse
38 gas emissions.²³ Between 1990 and 2015, total C sequestration in the LULUCF sector decreased by 16.0 percent,

²² LULUCF C Stock Change is the net C stock change from the following categories: *Forest Land Remaining Forest Land*, *Land Converted to Forest Land*, *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, *Land Converted to Grassland*, *Wetlands Remaining Wetlands*, *Land Converted to Wetlands*, *Settlements Remaining Settlements*, and *Land Converted to Settlements*.

²³ LULUCF emissions include the CO₂, CH₄, and N₂O emissions from *Peatlands Remaining Peatlands*; CH₄ and N₂O emissions reported for Non-CO₂ Emissions from Forest Fires, Non-CO₂ Emissions from Grassland Fires, and *Coastal Wetlands Remaining Coastal Wetlands*; CH₄ emissions from *Land Converted to Coastal Wetlands*; and N₂O Fluxes from Forest Soils and Settlement Soils.

1 primarily due to a decrease in the rate of net C accumulation in forests and an increase in emissions from *Land*
 2 *Converted to Grassland*.²⁴

3 Carbon dioxide removals are presented in Table ES-5 along with CO₂, CH₄, and N₂O emissions for LULUCF source
 4 categories. Lands undergoing peat extraction (i.e., *Peatlands Remaining Peatlands*) resulted in CO₂ emissions of 0.8
 5 MMT CO₂ Eq. (763 kt of CO₂). Forest fires were the largest source of CH₄ emissions from LULUCF in 2015,
 6 totaling 7.3 MMT CO₂ Eq. (292 kt of CH₄). *Coastal Wetlands Remaining Coastal Wetlands* resulted in CH₄
 7 emissions of 3.5 MMT CO₂ Eq. (141 kt of CH₄). Grassland fires resulted in CH₄ emissions of 0.4 MMT CO₂ Eq. (16
 8 kt of CH₄). *Peatlands Remaining Peatlands* and *Land Converted to Wetlands* resulted in CH₄ emissions of less than
 9 0.05 MMT CO₂ Eq.

10 Forest fires were also the largest source of N₂O emissions from LULUCF in 2015, totaling 4.8 MMT CO₂ Eq. (16 kt
 11 of N₂O). Nitrous oxide emissions from fertilizer application to settlement soils in 2015 totaled to 2.6 MMT CO₂ Eq.
 12 (9 kt of N₂O). This represents an increase of 81.5 percent since 1990. Additionally, the application of synthetic
 13 fertilizers to forest soils in 2015 resulted in N₂O emissions of 0.5 MMT CO₂ Eq. (2 kt of N₂O). Nitrous oxide
 14 emissions from fertilizer application to forest soils have increased by 455 percent since 1990, but still account for a
 15 relatively small portion of overall emissions. Grassland fires resulted in N₂O emissions of 0.4 MMT CO₂ Eq. (1 kt
 16 of N₂O). *Coastal Wetlands Remaining Coastal Wetlands* resulted in N₂O emissions of 0.1 MMT CO₂ Eq. (0.5 kt of
 17 N₂O), and *Peatlands Remaining Peatlands* resulted in N₂O emissions of less than 0.05 MMT CO₂ Eq.

LULUCF Sector Net Total^g	(449.1)	(315.3)	(375.1)	(387.7)	(370.4)	(368.8)	(366.4)

+ Absolute value does not exceed 0.05 MMT CO₂ Eq.

^a LULUCF C Stock Change is the net C stock change from the following categories: *Forest Land Remaining Forest Land, Land Converted to Forest Land, Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, Land Converted to Grassland, Wetlands Remaining Wetlands, Land Converted to Wetlands, Settlements Remaining Settlements, and Land Converted to Settlements.*

^b Includes the effects of net additions to stocks of carbon stored in forest ecosystem pools and harvested wood products.

^c Quality control uncovered errors in the estimate and uncertainty of soil C stock changes for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, and Land Converted to Grassland* sections in the LULUCF chapter of this report.

^d Estimates include emissions from N fertilizer additions on both *Settlements Remaining Settlements* and *Land Converted to Settlements*.

^e Estimates include emissions from N fertilizer additions on both *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*.

^f LULUCF emissions include the CO₂, CH₄, and N₂O emissions from *Peatlands Remaining Peatlands*; CH₄ and N₂O emissions reported for *Non-CO₂ Emissions from Forest Fires, Non-CO₂ Emissions from Grassland Fires, and Coastal Wetlands Remaining Coastal Wetlands*; CH₄ emissions from *Land Converted to Coastal Wetlands*; and N₂O Fluxes from *Forest Soils and Settlement Soils*.

^g The LULUCF Sector Net Total is the net sum of all emissions (i.e., sources) of greenhouse gases to the atmosphere plus removals of CO₂ (i.e., sinks or negative emissions) from the atmosphere.

Notes: Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

1 Waste

2 The Waste chapter contains emissions from waste management activities (except incineration of waste, which is
3 addressed in the Energy chapter). Landfills were the largest source of anthropogenic greenhouse gas emissions in the
4 Waste chapter, accounting for 83.0 percent of this chapter's emissions, and 17.7 percent of total U.S. CH₄
5 emissions.²⁵ Additionally, wastewater treatment accounts for 14.2 percent of Waste emissions, 2.3 percent of U.S.
6 CH₄ emissions, and 1.5 percent of U.S. N₂O emissions. Emissions of CH₄ and N₂O from composting are also
7 accounted for in this chapter, generating emissions of 2.1 MMT CO₂ Eq. and 1.9 MMT CO₂ Eq., respectively.
8 Overall, emission sources accounted for in the Waste chapter generated 2.1 percent of total U.S. greenhouse gas
9 emissions in 2015.

10 ES.4 Other Information

11 Emissions by Economic Sector

12 Throughout the *Inventory of U.S. Greenhouse Gas Emissions and Sinks* report, emission estimates are grouped into
13 five sectors (i.e., chapters) defined by the IPCC: Energy; Industrial Processes and Product Use; Agriculture;
14 LULUCF; and Waste. While it is important to use this characterization for consistency with UNFCCC reporting

²⁵ Landfills also store carbon, due to incomplete degradation of organic materials such as harvest wood products, yard trimmings, and food scraps, as described in the Land-Use, Land-Use Change, and Forestry chapter of the Inventory report.

1 guidelines, it is also useful to characterize emissions according to commonly used economic sector categories:
 2 residential, commercial, industry, transportation, electricity generation, agriculture, and U.S. Territories.
 3 Table ES-6 summarizes emissions from each of these economic sectors, and Figure ES-13 shows the trend in
 4 emissions by sector from 1990 to 2015.

5 **Figure ES-13: U.S. Greenhouse Gas Emissions Allocated to Economic Sectors (MMT CO₂ Eq.)**

6
7

8 **Table ES-6: U.S. Greenhouse Gas Emissions Allocated to Economic Sectors (MMT CO₂ Eq.)**

Economic Sectors	1990	2005	2011	2012	2013	2014	2015
Electric Power Industry	1,862.5	2,441.6	2,197.3	2,059.9	2,078.2	2,079.7	1,941.2
Transportation	1,551.3	2,001.0	1,800.0	1,780.7	1,790.2	1,803.4	1,803.7
Industry	1,629.5	1,469.3	1,378.5	1,365.2	1,412.8	1,426.0	1,436.7
Agriculture	526.7	574.3	592.0	577.6	567.5	566.1	570.3
Commercial	418.1	400.7	406.5	387.3	410.1	422.2	416.7
Residential	344.9	370.4	356.3	318.4	372.6	394.0	372.7
U.S. Territories	33.7	58.2	45.4	47.6	47.5	44.9	44.9
Total Emissions	6,366.7	7,315.6	6,776.0	6,536.8	6,678.9	6,736.3	6,586.2
LULUCF Sector Net Total^{a,b}	(449.1)	(315.3)	(375.1)	(387.7)	(370.4)	(368.8)	(366.4)
Net Emissions (Sources and Sinks)	5,917.6	7,000.3	6,400.9	6,149.1	6,308.5	6,367.5	6,219.8

Note: Total emissions presented without LULUCF. Total net emissions presented with LULUCF.

^a The LULUCF Sector Net Total is the net sum of all emissions (i.e., sources) of greenhouse gases to the atmosphere plus removals of CO₂ (i.e., sinks or negative emissions) from the atmosphere.

^b Quality control uncovered errors in the estimate and uncertainty of soil C stock changes for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, and *Land Converted to Grassland* sections in the LULUCF chapter of this report.

Notes: Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

9 Using this categorization, emissions from electricity generation accounted for the largest portion (29 percent) of
 10 total U.S. greenhouse gas emissions in 2015. Transportation activities, in aggregate, accounted for the second largest
 11 portion (27 percent), while emissions from industry accounted for the third largest portion (22 percent) of total U.S.
 12 greenhouse gas emissions in 2015. Emissions from industry have in general declined over the past decade, due to a
 13 number of factors, including structural changes in the U.S. economy (i.e., shifts from a manufacturing-based to a
 14 service-based economy), fuel switching, and energy efficiency improvements. The remaining 21 percent of U.S.

1 greenhouse gas emissions were contributed by, in order of magnitude, the agriculture, commercial, and residential
 2 sectors, plus emissions from U.S. Territories. Activities related to agriculture accounted for 9 percent of U.S.
 3 emissions; unlike other economic sectors, agricultural sector emissions were dominated by N₂O emissions from
 4 agricultural soil management and CH₄ emissions from enteric fermentation. The commercial and residential sectors
 5 accounted for 6 percent and 6 percent of emissions, respectively, and U.S. Territories accounted for 1 percent of
 6 emissions; emissions from these sectors primarily consisted of CO₂ emissions from fossil fuel combustion. CO₂ was
 7 also emitted and sequestered by a variety of activities related to forest management practices, tree planting in urban
 8 areas, the management of agricultural soils, landfilling of yard trimmings, and changes in C stocks in coastal
 9 wetlands.

10 Electricity is ultimately consumed in the economic sectors described above. Table ES-7 presents greenhouse gas
 11 emissions from economic sectors with emissions related to electricity generation distributed into end-use categories
 12 (i.e., emissions from electricity generation are allocated to the economic sectors in which the electricity is
 13 consumed). To distribute electricity emissions among end-use sectors, emissions from the source categories assigned
 14 to electricity generation were allocated to the residential, commercial, industry, transportation, and agriculture
 15 economic sectors according to retail sales of electricity.²⁶ These source categories include CO₂ from fossil fuel
 16 combustion and the use of limestone and dolomite for flue gas desulfurization, CO₂ and N₂O from incineration of
 17 waste, CH₄ and N₂O from stationary sources, and SF₆ from electrical transmission and distribution systems.

18 When emissions from electricity are distributed among these sectors, industrial activities and transportation account
 19 for the largest shares of U.S. greenhouse gas emissions (30 percent and 27 percent, respectively) in 2015. The
 20 residential and commercial sectors contributed the next largest shares of total U.S. greenhouse gas emissions in
 21 2015. Emissions from these sectors increase substantially when emissions from electricity are included, due to their
 22 relatively large share of electricity consumption (e.g., lighting, appliances). In all sectors except agriculture, CO₂
 23 accounts for more than 80 percent of greenhouse gas emissions, primarily from the combustion of fossil fuels.

24 Figure ES-14 shows the trend in these emissions by sector from 1990 to 2015.

25 **Table ES-7: U.S. Greenhouse Gas Emissions by Economic Sector with Electricity-Related**
 26 **Emissions Distributed (MMT CO₂ Eq.)**

Implied Sectors	1990	2005	2011	2012	2013	2014	2015
Industry	2,297.1	2,180.3	1,973.5	1,926.0	1,976.9	1,986.7	1,956.2
Transportation	1,554.4	2,005.9	1,804.3	1,784.7	1,794.3	1,807.5	1,807.5
Commercial	968.4	1,217.6	1,158.1	1,100.6	1,128.5	1,142.7	1,094.0
Residential	951.5	1,241.3	1,161.5	1,057.2	1,122.0	1,143.7	1,071.5
Agriculture	561.5	612.4	633.1	620.6	609.9	610.8	612.0
U.S. Territories	33.7	58.2	45.4	47.6	47.5	44.9	44.9
Total Emissions	6,366.7	7,315.6	6,776.0	6,536.8	6,678.9	6,736.3	6,586.2
LULUCF Sector Net Total^{a,b}	(449.1)	(315.3)	(375.1)	(387.7)	(370.4)	(368.8)	(366.4)
Net Emissions (Sources and Sinks)	5,917.6	7,000.3	6,400.9	6,149.1	6,308.5	6,367.5	6,219.8

^a The LULUCF Sector Total is the net sum of all emissions (i.e., sources) of greenhouse gases to the atmosphere plus removals of CO₂ (i.e., sinks or negative emissions) from the atmosphere.

^b Quality control uncovered errors in the estimate and uncertainty of soil C stock changes for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, and *Land Converted to Grassland* sections in the LULUCF chapter of this report.

Notes: Emissions from electricity generation are allocated based on aggregate electricity consumption in each end-use sector. Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

27

²⁶ Emissions were not distributed to U.S. Territories, since the electricity generation sector only includes emissions related to the generation of electricity in the 50 states and the District of Columbia.

Figure ES-14: U.S. Greenhouse Gas Emissions with Electricity-Related Emissions Distributed to Economic Sectors (MMT CO₂ Eq.)

Box ES-3: Recent Trends in Various U.S. Greenhouse Gas Emissions-Related Data

Total emissions can be compared to other economic and social indices to highlight changes over time. These comparisons include: (1) emissions per unit of aggregate energy consumption, because energy-related activities are the largest sources of emissions; (2) emissions per unit of fossil fuel consumption, because almost all energy-related emissions involve the combustion of fossil fuels; (3) emissions per unit of electricity consumption, because the electric power industry—utilities and non-utilities combined—was the largest source of U.S. greenhouse gas emissions in 2014; (4) emissions per unit of total gross domestic product as a measure of national economic activity; and (5) emissions per capita.

Table ES-8 provides data on various statistics related to U.S. greenhouse gas emissions normalized to 1990 as a baseline year. Greenhouse gas emissions in the United States have grown at an average annual rate of 0.2 percent since 1990. Since 1990, this rate is slightly slower than that for total energy and for fossil fuel consumption, and much slower than that for electricity consumption, overall gross domestic product and national population (see Figure ES-15).

Table ES-8: Recent Trends in Various U.S. Data (Index 1990 = 100)

Variable	1990	2005	2011	2012	2013	2014	2015	Avg. Annual Growth Rate
Greenhouse Gas Emissions ^a	100	115	106	103	105	106	103	0.2%
Energy Consumption ^b	100	118	115	112	115	117	115	0.6%

7

8 Key Categories

9 The 2006 IPCC Guidelines (IPCC 2006) defines a key category as a “[category] that is prioritized within the
10 national inventory system because its estimate has a significant influence on a country’s total inventory of
11 greenhouse gases in terms of the absolute level, the trend, or the uncertainty in emissions and removals.”²⁷ By
12 definition, key categories are sources or sinks that have the greatest contribution to the absolute overall level of
13 national emissions in any of the years covered by the time series. In addition, when an entire time series of emission
14 estimates is prepared, a thorough investigation of key categories must also account for the influence of trends of
15 individual source and sink categories. Finally, a qualitative evaluation of key categories should be performed, in
16 order to capture any key categories that were not identified in either of the quantitative analyses.

17 Figure ES-16 presents 2015 emission estimates for the key categories as defined by a level analysis (i.e., the
18 contribution of each source or sink category to the total inventory level). The UNFCCC reporting guidelines request
19 that key category analyses be reported at an appropriate level of disaggregation, which may lead to source and sink
20 category names which differ from those used elsewhere in the Inventory report. For more information regarding key
21 categories, see Section 1.5 – Key Categories and Annex 1.

 3 Note: For a complete discussion of the key category analysis, see Annex 1. Blue bars indicate either an Approach 1, or Approach
 4 1 and Approach 2 level assessment key category. Gray bars indicate solely an Approach 2 level assessment key category.

5 Quality Assurance and Quality Control (QA/QC)

6 The United States seeks to continually improve the quality, transparency, and credibility of the *Inventory of U.S.*
 7 *Greenhouse Gas Emissions and Sinks*. To assist in these efforts, the United States implemented a systematic
 8 approach to QA/QC. The procedures followed for the Inventory have been formalized in accordance with the
 9 *Quality Assurance/Quality Control and Uncertainty Management Plan (QA/QC Management Plan)* for the
 10 Inventory and the UNFCCC reporting guidelines.

11 Uncertainty Analysis of Emission Estimates

12 Uncertainty estimates are an essential element of a complete inventory of greenhouse gas emissions and removals,
 13 because they help to prioritize future work and improve overall quality. Some of the current estimates, such as those
 14 for CO₂ emissions from energy-related activities, are considered to have low uncertainties because the amount of
 15 CO₂ emitted is directly related to the amount of fuel consumed, the fraction of the fuel that is oxidized, and the
 16 carbon content of the fuel. For some other categories of emissions, however, a lack of or missing data,
 17 representativeness of data to real world conditions associated with the emissions/removal activities in United States,
 18 sampling errors, and measurement errors are example factors that contribute to the uncertainty associated with the
 19 estimates presented. Recognizing the benefit of conducting an uncertainty analysis, the UNFCCC reporting
 20 guidelines follow the recommendations of the *2006 IPCC Guidelines (IPCC 2006)*, Volume 1, Chapter 3 and require
 21 that countries provide single estimates of uncertainty for source and sink categories.

1 In addition to quantitative uncertainty assessments provided in accordance with UNFCCC reporting guidelines, a
2 qualitative discussion of uncertainty is presented for all source and sink categories. Within the discussion of each
3 emission source, specific factors affecting the uncertainty surrounding the estimates are discussed.

5 **Box ES-4: Recalculations of Inventory Estimates**

6 Each year, emission and sink estimates are recalculated and revised for all years in the *Inventory of U.S. Greenhouse*
7 *Gas Emissions and Sinks*, as attempts are made to improve both the analyses themselves, through the use of better
8 methods or data, and the overall usefulness of the report. In this effort, the United States follows the *2006 IPCC*
9 *Guidelines* (IPCC 2006), which states, “Both methodological changes and refinements over time are an essential
10 part of improving inventory quality. It is good practice to change or refine methods when: available data have
11 changed; the previously used method is not consistent with the IPCC guidelines for that category; a category has
12 become key; the previously used method is insufficient to reflect mitigation activities in a transparent manner; the
13 capacity for inventory preparation has increased; new inventory methods become available; and for correction of
14 errors.” In general, recalculations are made to the U.S. greenhouse gas emission estimates either to incorporate new
15 methodologies or, most commonly, to update recent historical data.

16 In each Inventory report, the results of all methodology changes and historical data updates are presented in the
17 Recalculations and Improvements chapter; detailed descriptions of each recalculation are contained within each
18 source's description contained in the report, if applicable. In general, when methodological changes have been
19 implemented, the entire time series (in the case of the most recent Inventory report, 1990 through 2014) has been
20 recalculated to reflect the change, per the *2006 IPCC Guidelines* (IPCC 2006). Changes in historical data are
21 generally the result of changes in statistical data supplied by other agencies. References for the data are provided for
22 additional information.

1. Introduction

This report presents estimates by the United States government of U.S. anthropogenic greenhouse gas emissions and sinks for the years 1990 through 2015. A summary of these estimates is provided in Table 2-1 and Table 2-2 by gas and source category in the Trends in Greenhouse Gas Emissions chapter. The emission estimates in these tables are presented on both a full molecular mass basis and on a Global Warming Potential (GWP) weighted basis¹ in order to show the relative contribution of each gas to global average radiative forcing. This report also discusses the methods and data used to calculate these emission estimates.

In 1992, the United States signed and ratified the United Nations Framework Convention on Climate Change (UNFCCC). As stated in Article 2 of the UNFCCC, “The ultimate objective of this Convention and any related legal instruments that the Conference of the Parties may adopt is to achieve, in accordance with the relevant provisions of the Convention, stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. Such a level should be achieved within a time-frame sufficient to allow ecosystems to adapt naturally to climate change, to ensure that food production is not threatened and to enable economic development to proceed in a sustainable manner.”^{2,3}

Parties to the Convention, by ratifying, “shall develop, periodically update, publish and make available...national inventories of anthropogenic emissions by sources and removals by sinks of all greenhouse gases not controlled by the Montreal Protocol, using comparable methodologies...”⁴ The United States views this report as an opportunity to fulfill these commitments under the UNFCCC.

In 1988, preceding the creation of the UNFCCC, the World Meteorological Organization (WMO) and the United Nations Environment Programme (UNEP) jointly established the Intergovernmental Panel on Climate Change (IPCC). The role of the IPCC is to assess on a comprehensive, objective, open and transparent basis the scientific, technical and socio-economic information relevant to understanding the scientific basis of risk of human-induced climate change, its potential impacts and options for adaptation and mitigation (IPCC 2014). Under Working Group 1 of the IPCC, nearly 140 scientists and national experts from more than thirty countries collaborated in the creation of the *Revised 1996 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC/UNEP/OECD/IEA 1997) to ensure that the emission inventories submitted to the UNFCCC are consistent and comparable between nations. The *IPCC Good Practice Guidance and Uncertainty Management in National Greenhouse Gas Inventories* and the *IPCC Good Practice Guidance for Land Use, Land-Use Change, and Forestry* further expanded upon the methodologies in the *Revised 1996 IPCC Guidelines*. In 2006, the IPCC accepted the *2006 Guidelines for National Greenhouse Gas Inventories* at its Twenty-Fifth Session (Mauritius, April 2006). The *2006 IPCC Guidelines* built

¹ More information provided in “Global Warming Potentials” section of this chapter on the use of *IPCC Fourth Assessment Report* (AR4) GWP values.

² The term “anthropogenic,” in this context, refers to greenhouse gas emissions and removals that are a direct result of human activities or are the result of natural processes that have been affected by human activities (IPCC 2006).

³ Article 2 of the Framework Convention on Climate Change published by the UNEP/WMO Information Unit on Climate Change. See <<http://unfccc.int>>. (UNEP/WMO 2000)

⁴ Article 4(1)(a) of the United Nations Framework Convention on Climate Change (also identified in Article 12). Subsequent decisions by the Conference of the Parties elaborated the role of Annex I Parties in preparing national inventories. See <<http://unfccc.int>>.

1 upon the previous bodies of work and include new sources and gases “...as well as updates to the previously
2 published methods whenever scientific and technical knowledge have improved since the previous guidelines were
3 issued. The UNFCCC adopted the *2006 IPCC Guidelines* as the standard methodological approach for Annex I
4 countries at the Nineteenth Conference of the Parties (Warsaw, November 11-23, 2013). This report presents
5 information in accordance with these guidelines.

6 Overall, this Inventory of anthropogenic greenhouse gas emissions and sinks provides a common and consistent
7 mechanism through which Parties to the UNFCCC can estimate emissions and compare the relative contribution of
8 individual sources, gases, and nations to climate change. The Inventory provides a national estimate of sources and
9 sinks for the United States, including all states and U.S. Territories.⁵ The structure of this report is consistent with
10 the current UNFCCC Guidelines on Annual Inventories (UNFCCC 2014) for Parties included in Annex I of the
11 Convention.

13 **Box 1-1: Methodological Approach for Estimating and Reporting U.S. Emissions and Sinks**

14 In following the UNFCCC requirement under Article 4.1 to develop and submit national greenhouse gas emissions
15 inventories, the gross emissions total presented in this report for the United States excludes emissions and sinks
16 from LULUCF. The net emissions total presented in this report for the United States includes emissions and sinks
17 from LULUCF. All emissions and sinks are calculated using internationally-accepted methods consistent with the
18 IPCC Guidelines.⁶ Additionally, the calculated emissions and sinks in a given year for the United States are
19 presented in a common manner in line with the UNFCCC reporting guidelines for the reporting of inventories under
20 this international agreement.⁷ The use of consistent methods to calculate emissions and sinks by all nations
21 providing their inventories to the UNFCCC ensures that these reports are comparable. In this regard, U.S. emissions
22 and sinks reported in this Inventory are comparable to emissions and sinks reported by other countries. The report
23 itself follows this standardized format, and provides an explanation of the IPCC methods used to calculate emissions
24 and sinks, and the manner in which those calculations are conducted.

25 On October 30, 2009, the U.S. Environmental Protection Agency (EPA) published a rule for the mandatory
26 reporting of greenhouse gases from large greenhouse gas emissions sources in the United States. Implementation of
27 40 CFR Part 98 is referred to as the EPA’s GHGRP. 40 CFR Part 98 applies to direct greenhouse gas emitters, fossil
28 fuel suppliers, industrial gas suppliers, and facilities that inject CO₂ underground for sequestration or other reasons.⁸
29 Reporting is at the facility level, except for certain suppliers of fossil fuels and industrial greenhouse gases. The
30 GHGRP dataset and the data presented in this Inventory are complementary.

31 The GHGRP data set continues to be an important resource for the Inventory, providing not only annual emissions
32 information, but also other annual information, such as activity data and emissions factors that can improve and
33 refine national emission estimates and trends over time. GHGRP data also allow EPA to disaggregate national
34 Inventory estimates in new ways that can highlight differences across regions and sub-categories of emissions. The
35 GHGRP will continue to enhance QA/QC procedures and assessment of uncertainties.

36 EPA continues to analyze the data on an annual basis to improve the national estimates presented in this Inventory
37 and uses that data for a number of categories consistent with IPCC guidance.⁹ EPA has integrated GHGRP
38 information for several categories¹⁰ this year and also identifies other categories¹¹ where EPA plans to integrate

⁵ U.S. Territories include American Samoa, Guam, Puerto Rico, U.S. Virgin Islands, Wake Island, and other U.S. Pacific Islands.

3 1.1 Background Information

4 Science

5 For over the past 200 years, the burning of fossil fuels such as coal and oil, deforestation, land-use changes, and
6 other sources have caused the concentrations of heat-trapping "greenhouse gases" to increase significantly in our
7 atmosphere (NOAA 2017). These gases in the atmosphere absorb some of the energy being radiated from the
8 surface of the Earth and then re-radiate this energy with some returning to the Earth's surface, essentially acting like
9 a blanket that makes the Earth's surface warmer than it would be otherwise.

10 Greenhouse gases are necessary to life as we know it. Without greenhouse gases in the atmosphere, the planet's
11 surface would be about 60 degrees Fahrenheit cooler than present (EPA 2009). Carbon dioxide is also necessary for
12 plant growth. With emissions from biological and geological sources, there is a natural level of greenhouse gases
13 that is maintained in the atmosphere. But, as the concentrations of these gases continue to increase in from man-
14 made sources, the Earth's temperature is climbing above past levels. The Earth's average land and ocean surface
15 temperature has increased by about 1.2 to 1.9 degrees Fahrenheit since 1880. The last three decades have each been
16 the warmest decade successively at the Earth's surface since 1850 (IPCC 2013). Most of the warming in recent
17 decades is very likely the result of human activities. Other aspects of the climate are also changing such as rainfall
18 patterns, snow and ice cover, and sea level.

19 If greenhouse gases continue to increase, climate models predict that the average temperature at the Earth's surface
20 is likely to increase from 0.5 to 8.6 degrees Fahrenheit above 1986 through 2005 levels by the end of this century,
21 depending on future emissions (IPCC 2013). Scientists are certain that human activities are changing the
22 composition of the atmosphere, and that increasing the concentration of greenhouse gases will change the planet's
23 climate. However, they are not sure by how much it will change, at what rate it will change, or what the exact effects
24 will be.¹²

25 Greenhouse Gases

26 Although the Earth's atmosphere consists mainly of oxygen and nitrogen, neither plays a significant role in
27 enhancing the greenhouse effect because both are essentially transparent to terrestrial radiation. The greenhouse
28 effect is primarily a function of the concentration of water vapor, carbon dioxide (CO₂), methane (CH₄), nitrous
29 oxide (N₂O), and other trace gases in the atmosphere that absorb the terrestrial radiation leaving the surface of the
30 Earth (IPCC 2013). Changes in the atmospheric concentrations of these greenhouse gases can alter the balance of
31 energy transfers between the space and the earth system.¹³ A gauge of these changes is called radiative forcing,
32 which is a measure of the influence a perturbation has in altering the balance of incoming and outgoing energy in the
33 Earth-atmosphere system (IPCC 2013). Holding everything else constant, increases in greenhouse gas
34 concentrations in the atmosphere will produce positive radiative forcing (i.e., a net increase in the absorption of
35 energy by the Earth).

36 *Human activities are continuing to affect the Earth's energy budget by changing the emissions and*
37 *resulting atmospheric concentrations of radiatively important gases and aerosols and by changing land*
38 *surface properties (IPCC 2013).*

39 Naturally occurring greenhouse gases include water vapor, CO₂, CH₄, N₂O, and ozone (O₃). Several classes of
40 halogenated substances that contain fluorine, chlorine, or bromine are also greenhouse gases, but they are, for the

¹² For more information see <<http://www.epa.gov/climatechange/science>>.

¹³ For more on the science of climate change, see NRC (2012).

1 most part, solely a product of industrial activities. Chlorofluorocarbons (CFCs) and hydrochlorofluorocarbons
 2 (HCFCs) are halocarbons that contain chlorine, while halocarbons that contain bromine are referred to as
 3 bromofluorocarbons (i.e., halons). As stratospheric ozone depleting substances, CFCs, HCFCs, and halons are
 4 covered under the Montreal Protocol on Substances that Deplete the Ozone Layer. The UNFCCC defers to this
 5 earlier international treaty. Consequently, Parties to the UNFCCC are not required to include these gases in national
 6 greenhouse gas inventories.¹⁴ Some other fluorine-containing halogenated substances—hydrofluorocarbons (HFCs),
 7 perfluorocarbons (PFCs), sulfur hexafluoride (SF₆), and nitrogen trifluoride (NF₃)—do not deplete stratospheric
 8 ozone but are potent greenhouse gases. These latter substances are addressed by the UNFCCC and accounted for in
 9 national greenhouse gas inventories.

10 There are also several other substances that influence the global radiation budget but are short-lived and therefore
 11 not well-mixed. These substances include carbon monoxide (CO), nitrogen dioxide (NO₂), sulfur dioxide (SO₂), and
 12 tropospheric (ground level) O₃. Tropospheric ozone is formed by two precursor pollutants, volatile organic
 13 compounds (VOCs) and nitrogen oxides (NO_x) in the presence of ultraviolet light (sunlight).

14 Aerosols are extremely small particles or liquid droplets suspended in the Earth’s atmosphere that are often
 15 composed of sulfur compounds, carbonaceous combustion products (e.g., black carbon), crustal materials (e.g., dust)
 16 and other human induced pollutants. They can affect the absorptive characteristics of the atmosphere (e.g., scattering
 17 incoming sunlight away from the Earth’s surface, or, in the case of black carbon, absorb sunlight) and can play a
 18 role in affecting cloud formation and lifetime affecting the radiative forcing of clouds and precipitation patterns.
 19 Comparatively, however, while the understanding of aerosols has increased in recent years, they still account for the
 20 largest contribution to uncertainty estimates in global energy budgets (IPCC 2013).

21 Carbon dioxide, CH₄, and N₂O are continuously emitted to and removed from the atmosphere by natural processes
 22 on Earth. Anthropogenic activities, however, can cause additional quantities of these and other greenhouse gases to
 23 be emitted or sequestered, thereby changing their global average atmospheric concentrations. Natural activities such
 24 as respiration by plants or animals and seasonal cycles of plant growth and decay are examples of processes that
 25 only cycle carbon or nitrogen between the atmosphere and organic biomass. Such processes, except when directly or
 26 indirectly perturbed out of equilibrium by anthropogenic activities, generally do not alter average atmospheric
 27 greenhouse gas concentrations over decadal timeframes. Climatic changes resulting from anthropogenic activities,
 28 however, could have positive or negative feedback effects on these natural systems. Atmospheric concentrations of
 29 these gases, along with their rates of growth and atmospheric lifetimes, are presented in Table 1-1.

30 **Table 1-1: Global Atmospheric Concentration, Rate of Concentration Change, and**
 31 **Atmospheric Lifetime of Selected Greenhouse Gases**

Atmospheric Variable	CO ₂	CH ₄	N ₂ O	SF ₆	CF ₄
Pre-industrial atmospheric concentration	280 ppm	0.700 ppm	0.270 ppm	0 ppt	40 ppt
Atmospheric concentration	404 ppm ^a	1.834 ppm ^b	0.328 ppm ^b	8.6 ppt ^b	79 ppt ^c
Rate of concentration change	2.4 ppm/yr	5 ppb/yr ^{d,e}	0.8 ppb/yr ^e	0.27 ppt/yr ^e	0.7 ppt/yr ^e
Atmospheric lifetime (years)	See footnote ^f	12.4 ^g	121 ^g	3,200	50,000

^a The atmospheric CO₂ concentration is the 2016 annual average at the Mauna Loa, HI station (NOAA/ESRL 2017).

^b The values presented are global 2015 annual average mole fractions (CDIAC 2016).

^c The 2011 CF₄ global mean atmospheric concentration is from the Advanced Global Atmospheric Gases Experiment (IPCC 2013).

^d The growth rate for atmospheric CH₄ decreased from over 10 ppb/yr in the 1980s to nearly zero in the early 2000s; recently, the growth rate has been about 5 ppb/year.

^e The rate of concentration change is the average rate of change between 2005 and 2011 (IPCC 2013).

^f For a given amount of carbon dioxide emitted, some fraction of the atmospheric increase in concentration is quickly absorbed by the oceans and terrestrial vegetation, some fraction of the atmospheric increase will only slowly decrease over a number of years, and a small portion of the increase will remain for many centuries or more.

^g This lifetime has been defined as an “adjustment time” that takes into account the indirect effect of the gas on its own residence time.

Source: Pre-industrial atmospheric concentrations, atmospheric lifetime, and rate of concentration changes for CH₄, N₂O, SF₆, and CF₄ are from IPCC (2013). The rate of concentration change for CO₂ is an average of the rates from 2011 through 2016 has

¹⁴ Emissions estimates of CFCs, HCFCs, halons and other ozone-depleting substances are included in this document for informational purposes.

fluctuated between 1.9 to 3.0 ppm per year over this period (NOAA/ESRL 2017).

1 A brief description of each greenhouse gas, its sources, and its role in the atmosphere is given below. The following
2 section then explains the concept of GWPs, which are assigned to individual gases as a measure of their relative
3 average global radiative forcing effect.

4 *Water Vapor (H₂O)*. Water vapor is the largest contributor to the natural greenhouse effect. Water vapor is
5 fundamentally different from other greenhouse gases in that it can condense and rain out when it reaches high
6 concentrations, and the total amount of water vapor in the atmosphere is in part a function of the Earth's
7 temperature. While some human activities such as evaporation from irrigated crops or power plant cooling release
8 water vapor into the air, this has been determined to have a negligible effect on climate (IPCC 2013). The lifetime of
9 water vapor in the troposphere is on the order of 10 days. Water vapor can also contribute to cloud formation, and
10 clouds can have both warming and cooling effects by either trapping or reflecting heat. Because of the relationship
11 between water vapor levels and temperature, water vapor and clouds serve as a feedback to climate change, such
12 that for any given increase in other greenhouse gases, the total warming is greater than would happen in the absence
13 of water vapor. Aircraft contrails, which consist of water vapor and other substances, are aviation-induced clouds
14 with the same radiative forcing effects as high-altitude cirrus clouds (IPCC 1999).

15 *Carbon Dioxide (CO₂)*. In nature, carbon is cycled between various atmospheric, oceanic, land biotic, marine biotic,
16 and mineral reservoirs. The largest fluxes occur between the atmosphere and terrestrial biota, and between the
17 atmosphere and surface water of the oceans. In the atmosphere, carbon predominantly exists in its oxidized form as
18 CO₂. Atmospheric CO₂ is part of this global carbon cycle, and therefore its fate is a complex function of
19 geochemical and biological processes. Carbon dioxide concentrations in the atmosphere increased from
20 approximately 280 parts per million by volume (ppmv) in pre-industrial times to 404 ppmv in 2016, a 44 percent
21 increase (IPCC 2013 and NOAA/ESRL 2017).^{15,16} The IPCC definitively states that “the increase of CO₂ ... is
22 caused by anthropogenic emissions from the use of fossil fuel as a source of energy and from land use and land use
23 changes, in particular agriculture” (IPCC 2013). The predominant source of anthropogenic CO₂ emissions is the
24 combustion of fossil fuels. Forest clearing, other biomass burning, and some non-energy production processes (e.g.,
25 cement production) also emit notable quantities of CO₂. In its *Fifth Assessment Report*, the IPCC stated “it is
26 extremely likely that more than half of the observed increase in global average surface temperature from 1951 to
27 2010 was caused by the anthropogenic increase in greenhouse gas concentrations and other anthropogenic forcings
28 together,” of which CO₂ is the most important (IPCC 2013).

29 *Methane (CH₄)*. Methane is primarily produced through anaerobic decomposition of organic matter in biological
30 systems. Agricultural processes such as wetland rice cultivation, enteric fermentation in animals, and the
31 decomposition of animal wastes emit CH₄, as does the decomposition of municipal solid wastes. Methane is also
32 emitted during the production and distribution of natural gas and petroleum, and is released as a by-product of coal
33 mining and incomplete fossil fuel combustion. Atmospheric concentrations of CH₄ have increased by about 162
34 percent since 1750, from a pre-industrial value of about 700 ppb to 1,834 ppb in 2015¹⁷ although the rate of increase
35 decreased to near zero in the early 2000s, and has recently increased again to about 5 ppb/year. The IPCC has
36 estimated that slightly more than half of the current CH₄ flux to the atmosphere is anthropogenic, from human
37 activities such as agriculture, fossil fuel use, and waste disposal (IPCC 2007).

38 Methane is primarily removed from the atmosphere through a reaction with the hydroxyl radical (OH) and is
39 ultimately converted to CO₂. Minor removal processes also include reaction with chlorine in the marine boundary
40 layer, a soil sink, and stratospheric reactions. Increasing emissions of CH₄ reduce the concentration of OH, a
41 feedback that increases the atmospheric lifetime of CH₄ (IPCC 2013). Methane's reactions in the atmosphere also
42 lead to production of tropospheric ozone and stratospheric water vapor, both of which also contribute to climate
43 change.

¹⁵ The pre-industrial period is considered as the time preceding the year 1750 (IPCC 2013).

¹⁶ Carbon dioxide concentrations during the last 1,000 years of the pre-industrial period (i.e., 750 to 1750), a time of relative climate stability, fluctuated by about ±10 ppmv around 280 ppmv (IPCC 2013).

¹⁷ This value is the global 2015 annual average mole fraction (CDIAC 2016).

1 *Nitrous Oxide (N₂O)*. Anthropogenic sources of N₂O emissions include agricultural soils, especially production of
2 nitrogen-fixing crops and forages, the use of synthetic and manure fertilizers, and manure deposition by livestock;
3 fossil fuel combustion, especially from mobile combustion; adipic (nylon) and nitric acid production; wastewater
4 treatment and waste incineration; and biomass burning. The atmospheric concentration of N₂O has increased by 21
5 percent since 1750, from a pre-industrial value of about 270 ppb to 328 ppb in 2015,¹⁸ a concentration that has not
6 been exceeded during the last 800 thousand years. Nitrous oxide is primarily removed from the atmosphere by the
7 photolytic action of sunlight in the stratosphere (IPCC 2013).

8 *Ozone (O₃)*. Ozone is present in both the upper stratosphere,¹⁹ where it shields the Earth from harmful levels of
9 ultraviolet radiation, and at lower concentrations in the troposphere,²⁰ where it is the main component of
10 anthropogenic photochemical “smog.” During the last two decades, emissions of anthropogenic chlorine and
11 bromine-containing halocarbons, such as CFCs, have depleted stratospheric ozone concentrations. This loss of
12 ozone in the stratosphere has resulted in negative radiative forcing, representing an indirect effect of anthropogenic
13 emissions of chlorine and bromine compounds (IPCC 2013). The depletion of stratospheric ozone and its radiative
14 forcing was expected to reach a maximum in about 2000 before starting to recover.

15 The past increase in tropospheric ozone, which is also a greenhouse gas, is estimated to provide the fourth largest
16 increase in direct radiative forcing since the pre-industrial era, behind CO₂, black carbon, and CH₄. Tropospheric
17 ozone is produced from complex chemical reactions of volatile organic compounds (including CH₄) mixing with
18 NO_x in the presence of sunlight. The tropospheric concentrations of ozone and these other pollutants are short-lived
19 and, therefore, spatially variable (IPCC 2013).

20 *Halocarbons, Sulfur Hexafluoride, and Nitrogen Trifluoride*. Halocarbons are, for the most part, man-made
21 chemicals that have direct radiative forcing effects and could also have an indirect effect. Halocarbons that contain
22 chlorine (CFCs, HCFCs, methyl chloroform, and carbon tetrachloride) and bromine (halons, methyl bromide, and
23 hydrobromofluorocarbons) result in stratospheric ozone depletion and are therefore controlled under the Montreal
24 Protocol on Substances that Deplete the Ozone Layer. Although most CFCs and HCFCs are potent global warming
25 gases, their net radiative forcing effect on the atmosphere is reduced because they cause stratospheric ozone
26 depletion, which itself is a greenhouse gas but which also shields the Earth from harmful levels of ultraviolet
27 radiation. Under the Montreal Protocol, the United States phased out the production and importation of halons by
28 1994 and of CFCs by 1996. Under the Copenhagen Amendments to the Protocol, a cap was placed on the production
29 and importation of HCFCs by non-Article 5²¹ countries, including the U.S., beginning in 1996, and then followed by
30 intermediate requirements and a complete phase-out by the year 2030. While ozone depleting gases covered under
31 the Montreal Protocol and its Amendments are not covered by the UNFCCC, they are reported in this Inventory
32 under Annex 6.2 for informational purposes.

33 Hydrofluorocarbons, PFCs, SF₆, and NF₃ are not ozone depleting substances. The most common HFCs are,
34 however, powerful greenhouse gases. Hydrofluorocarbons are primarily used as replacements for ozone depleting
35 substances but also emitted as a by-product of the HCFC-22 (chlorodifluoromethane) manufacturing process.
36 Currently, they have a small aggregate radiative forcing impact, but it is anticipated that without further controls
37 their contribution to overall radiative forcing will increase (IPCC 2013). An amendment to the Montreal Protocol

¹⁸ This value is the global 2015 annual average (CDIAC 2016).

¹⁹ The stratosphere is the layer from the troposphere up to roughly 50 kilometers. In the lower regions the temperature is nearly constant but in the upper layer the temperature increases rapidly because of sunlight absorption by the ozone layer. The ozone-layer is the part of the stratosphere from 19 kilometers up to 48 kilometers where the concentration of ozone reaches up to 10 parts per million.

²⁰ The troposphere is the layer from the ground up to 11 kilometers near the poles and up to 16 kilometers in equatorial regions (i.e., the lowest layer of the atmosphere where people live). It contains roughly 80 percent of the mass of all gases in the atmosphere and is the site for most weather processes, including most of the water vapor and clouds.

²¹ Article 5 of the Montreal Protocol covers several groups of countries, especially developing countries, with low consumption rates of ozone depleting substances. Developing countries with per capita consumption of less than 0.3 kg of certain ozone depleting substances (weighted by their ozone depleting potential) receive financial assistance and a grace period of ten additional years in the phase-out of ozone depleting substances.

1 was adopted in 2016 which includes obligations for all countries to phase down the production and consumption of
2 HFCs.

3 Perfluorocarbons, SF₆, and NF₃ are predominantly emitted from various industrial processes including aluminum
4 smelting, semiconductor manufacturing, electric power transmission and distribution, and magnesium casting.
5 Currently, the radiative forcing impact of PFCs, SF₆, and NF₃ is also small, but they have a significant growth rate,
6 extremely long atmospheric lifetimes, and are strong absorbers of infrared radiation, and therefore have the potential
7 to influence climate far into the future (IPCC 2013).

8 *Carbon Monoxide (CO)*. Carbon monoxide has an indirect radiative forcing effect by elevating concentrations of
9 CH₄ and tropospheric ozone through chemical reactions with other atmospheric constituents (e.g., the hydroxyl
10 radical, OH) that would otherwise assist in destroying CH₄ and tropospheric ozone. Carbon monoxide is created
11 when carbon-containing fuels are burned incompletely. Through natural processes in the atmosphere, it is eventually
12 oxidized to CO₂. Carbon monoxide concentrations are both short-lived in the atmosphere and spatially variable.

13 *Nitrogen Oxides (NO_x)*. The primary climate change effects of nitrogen oxides (i.e., NO and NO₂) are indirect and
14 result from their role in promoting the formation of ozone in the troposphere, are a precursor to nitrate particles (i.e.,
15 aerosols) and, to a lesser degree, lower stratosphere, where they have positive radiative forcing effects.²²
16 Additionally, NO_x emissions are also likely to decrease CH₄ concentrations, thus having a negative radiative forcing
17 effect (IPCC 2013). Nitrogen oxides are created from lightning, soil microbial activity, biomass burning (both
18 natural and anthropogenic fires) fuel combustion, and, in the stratosphere, from the photo-degradation of N₂O.
19 Concentrations of NO_x are both relatively short-lived in the atmosphere and spatially variable.

20 *Non-methane Volatile Organic Compounds (NMVOCs)*. Non-methane volatile organic compounds include
21 substances such as propane, butane, and ethane. These compounds participate, along with NO_x, in the formation of
22 tropospheric ozone and other photochemical oxidants. NMVOCs are emitted primarily from transportation and
23 industrial processes, as well as biomass burning and non-industrial consumption of organic solvents. Concentrations
24 of NMVOCs tend to be both short-lived in the atmosphere and spatially variable.

25 *Aerosols*. Aerosols are extremely small particles or liquid droplets found in the atmosphere that are either directly
26 emitted into or are created through chemical reactions in the Earth's atmosphere. Aerosols or their chemical
27 precursors can be emitted by natural events such as dust storms and volcanic activity, or by anthropogenic processes
28 such as fuel combustion and biomass burning. Various categories of aerosols exist, including naturally produced
29 aerosols such as soil dust, sea salt, biogenic aerosols, sulfates, nitrates, and volcanic aerosols, and anthropogenically
30 manufactured aerosols such as industrial dust and carbonaceous²³ aerosols (e.g., black carbon, organic carbon) from
31 transportation, coal combustion, cement manufacturing, waste incineration, and biomass burning. Aerosols can be
32 removed from the atmosphere relatively rapidly by precipitation or through more complex processes under dry
33 conditions.

34 Aerosols affect radiative forcing differently than greenhouse gases. Their radiative effects occur through direct and
35 indirect mechanisms: directly by scattering and absorbing solar radiation (and to a lesser extent scattering,
36 absorption, and emission of terrestrial radiation); and indirectly by increasing cloud droplets and ice crystals that
37 modify the formation, precipitation efficiency, and radiative properties of clouds (IPCC 2013). Despite advances in
38 understanding of cloud-aerosol interactions, the contribution of aerosols to radiative forcing are difficult to quantify
39 because aerosols generally have short atmospheric lifetimes, and have number concentrations, size distributions, and
40 compositions that vary regionally, spatially, and temporally (IPCC 2013).

41 The net effect of aerosols on the Earth's radiative forcing is believed to be negative (i.e., net cooling effect on the
42 climate). In fact, "despite the large uncertainty ranges on aerosol forcing, there is high confidence that aerosols have
43 offset a substantial portion of GHG forcing" (IPCC 2013).²⁴ Although because they remain in the atmosphere for

²² NO_x emissions injected higher in the stratosphere, primarily from fuel combustion emissions from high altitude supersonic aircraft, can lead to stratospheric ozone depletion.

²³ Carbonaceous aerosols are aerosols that are comprised mainly of organic substances and forms of black carbon (or soot) (IPCC 2013).

²⁴ The IPCC (2013) defines high confidence as an indication of strong scientific evidence and agreement in this statement.

1 only days to weeks, their concentrations respond rapidly to changes in emissions.²⁵ Not all aerosols have a cooling
2 effect. Current research suggests that another constituent of aerosols, black carbon, has a positive radiative forcing
3 by heating the Earth’s atmosphere and causing surface warming when deposited on ice and snow (IPCC 2013).
4 Black carbon also influences cloud development, but the direction and magnitude of this forcing is an area of active
5 research.

6 Global Warming Potentials

7 A global warming potential is a quantified measure of the globally averaged relative radiative forcing impacts of a
8 particular greenhouse gas (see Table 1-2). It is defined as the accumulated radiative forcing within a specific time
9 horizon caused by emitting 1 kilogram (kg) of the gas, relative to that of the reference gas CO₂ (IPCC 2014). Direct
10 radiative effects occur when the gas itself absorbs radiation. Indirect radiative forcing occurs when chemical
11 transformations involving the original gas produce a gas or gases that are greenhouse gases, or when a gas
12 influences other radiatively important processes such as the atmospheric lifetimes of other gases. The reference gas
13 used is CO₂, and therefore GWP-weighted emissions are measured in million metric tons of CO₂ equivalent (MMT
14 CO₂ Eq.).²⁶ The relationship between kilotons (kt) of a gas and MMT CO₂ Eq. can be expressed as follows:

$$15 \quad MMT \text{ CO}_2 \text{ Eq.} = (kt \text{ of gas}) \times (GWP) \times \left(\frac{MMT}{1,000 \text{ kt}} \right)$$

16 where,

17 MMT CO₂ Eq. = Million metric tons of CO₂ equivalent

18 kt = kilotons (equivalent to a thousand metric tons)

19 GWP = Global warming potential

20 MMT = Million metric tons

21 GWP values allow for a comparison of the impacts of emissions and reductions of different gases. According to the
22 IPCC, GWPs typically have an uncertainty of ±35 percent. Parties to the UNFCCC have also agreed to use GWPs
23 based upon a 100-year time horizon, although other time horizon values are available.

24 *...the global warming potential values used by Parties included in Annex I to the Convention (Annex I*
25 *Parties) to calculate the carbon dioxide equivalence of anthropogenic emissions by sources and removals*
26 *by sinks of greenhouse gases shall be those listed in the column entitled “Global warming potential for*
27 *given time horizon” in table 2.14 of the errata to the contribution of Working Group I to the Fourth*
28 *Assessment Report of the Intergovernmental Panel on Climate Change, based on the effects of greenhouse*
29 *gases over a 100-year time horizon...²⁷*

30 Greenhouse gases with relatively long atmospheric lifetimes (e.g., CO₂, CH₄, N₂O, HFCs, PFCs, SF₆, NF₃) tend to
31 be evenly distributed throughout the atmosphere, and consequently global average concentrations can be
32 determined. The short-lived gases such as water vapor, carbon monoxide, tropospheric ozone, ozone precursors
33 (e.g., NO_x, and NMVOCs), and tropospheric aerosols (e.g., SO₂ products and carbonaceous particles), however,
34 vary regionally, and consequently it is difficult to quantify their global radiative forcing impacts. Parties to the
35 UNFCCC have not agreed upon GWP values for these gases that are short-lived and spatially inhomogeneous in the
36 atmosphere.

²⁵ Volcanic activity can inject significant quantities of aerosol producing sulfur dioxide and other sulfur compounds into the stratosphere, which can result in a longer negative forcing effect (i.e., a few years) (IPCC 2013).

²⁶ Carbon comprises 12/44^{ths} of carbon dioxide by weight.

²⁷ Framework Convention on Climate Change; Available online at: <<http://unfccc.int/resource/docs/2013/cop19/eng/10a03.pdf>>; 31 January 2014; Report of the Conference of the Parties at its nineteenth session; held in Warsaw from 11 to 23 November 2013; Addendum; Part two: Action taken by the Conference of the Parties at its nineteenth session; Decision 24/CP.19; Revision of the UNFCCC reporting guidelines on annual inventories for Parties included in Annex I to the Convention; p. 2. (UNFCCC 2014).

1 **Table 1-2: Global Warming Potentials and Atmospheric Lifetimes (Years) Used in this Report**

Gas	Atmospheric Lifetime	GWP ^c
CO ₂	^b	1
CH ₄ ^a	12	25
N ₂ O	114	298
HFC-23	270	14,800
HFC-32	4.9	675
HFC-125	29	3,500
HFC-134a	14	1,430
HFC-143a	52	4,470
HFC-152a	1.4	124
HFC-227ea	34.2	3,220
HFC-236fa	240	9,810
HFC-4310mee	15.9	1,640
CF ₄	50,000	7,390
C ₂ F ₆	10,000	12,200
C ₄ F ₁₀	2,600	8,860
C ₆ F ₁₄	3,200	9,300
SF ₆	3,200	22,800
NF ₃	740	17,200

^a The GWP of CH₄ includes the direct effects and those indirect effects due to the production of tropospheric ozone and stratospheric water vapor. The indirect effect due to the production of CO₂ is not included.

^b For a given amount of carbon dioxide emitted, some fraction of the atmospheric increase in concentration is quickly absorbed by the oceans and terrestrial vegetation, some fraction of the atmospheric increase will only slowly decrease over a number of years, and a small portion of the increase will remain for many centuries or more.

^c 100-year time horizon.

2

3 **Box 1-2: The IPCC Fifth Assessment Report and Global Warming Potentials**

4 In 2014, the IPCC published its *Fifth Assessment Report (AR5)*, which updated its comprehensive scientific
5 assessment of climate change. Within the AR5 report, the GWP values of several gases were revised relative to
6 previous IPCC reports, namely the *IPCC Second Assessment Report (SAR)* (IPCC 1996), the *IPCC Third*
7 *Assessment Report (TAR)* (IPCC 2001), and the *IPCC Fourth Assessment Report (AR4)* (IPCC 2007). Although the
8 AR4 GWP values are used throughout this report, consistent with UNFCCC reporting requirements, it is straight-
9 forward to review the changes to the GWP values and their impact on estimates of the total GWP-weighted
10 emissions of the United States. In the AR5, the IPCC applied an improved calculation of CO₂ radiative forcing and
11 an improved CO₂ response function in presenting updated GWP values. Additionally, the atmospheric lifetimes of
12 some gases have been recalculated, and updated background concentrations were used. In addition, the values for
13 radiative forcing and lifetimes have been recalculated for a variety of halocarbons, and the indirect effects of
14 methane on ozone have been adjusted to match more recent science. Table 1-3 presents the new GWP values,
15 relative to those presented in the AR4 and using the 100-year time horizon common to UNFCCC reporting.

16 For consistency with international reporting standards under the UNFCCC, official emission estimates are reported
17 by the United States using AR4 GWP values, as required by the 2013 revision to the UNFCCC reporting guidelines
18 for national inventories.²⁸ All estimates provided throughout this report are also presented in unweighted units. For

²⁸ See <<http://unfccc.int/resource/docs/2013/cop19/eng/10a03.pdf>>.

1 informational purposes, emission estimates that use GWPs from other IPCC Assessment Reports are presented in
 2 detail in Annex 6.1 of this report.

3

4 **Table 1-3: Comparison of 100-Year GWP values**

Gas	SAR	AR4	AR5 ^a	AR5 with feedbacks ^b	Comparison to AR4		
					SAR	AR5	AR5 with feedbacks ^b

5

6 1.2 National Inventory Arrangements

7 The U.S. Environmental Protection Agency (EPA), in cooperation with other U.S. government agencies, prepares
 8 the *Inventory of U.S. Greenhouse Gas Emissions and Sinks*. A wide range of agencies and individuals are involved
 9 in supplying data to, planning methodological approaches and improvements, reviewing, or preparing portions of the
 10 U.S. Inventory—including federal and state government authorities, research and academic institutions, industry
 11 associations, and private consultants.

12 Within EPA, the Office of Atmospheric Programs (OAP) is the lead office responsible for the emission calculations
 13 provided in the Inventory, as well as the completion of the National Inventory Report and the Common Reporting
 14 Format tables. EPA's Office of Transportation and Air Quality (OTAQ) and Greenhouse Gas Reporting Program

1 (GHGRP) (within OAP) are also involved in calculating emissions for the Inventory. While the U.S. Department of
2 State officially submits the annual Inventory to the UNFCCC, EPA's OAP serves as the Inventory focal point for
3 technical questions and comments on the U.S. Inventory. The staff of OAP and OTAQ coordinates the annual
4 methodological choice, activity data collection, and emission calculations at the individual source category level.
5 Within OAP, an inventory coordinator compiles the entire Inventory into the proper reporting format for submission
6 to the UNFCCC, and is responsible for the collection and consistency of cross-cutting issues in the Inventory.

7 Several other government agencies contribute to the collection and analysis of the underlying activity data used in
8 the Inventory calculations. Formal relationships exist between EPA and other U.S. agencies that provide official
9 data for use in the Inventory. The U.S. Department of Energy's Energy Information Administration provides
10 national fuel consumption data and the U.S. Department of Defense provides military fuel consumption and bunker
11 fuels. Informal relationships also exist with other U.S. agencies to provide activity data for use in EPA's emission
12 calculations. These include: the U.S. Department of Agriculture, the U.S. Geological Survey, the Federal Highway
13 Administration, the Department of Transportation, the Bureau of Transportation Statistics, the Department of
14 Commerce, the National Agricultural Statistics Service, and the Federal Aviation Administration. EPA also uses
15 emissions and other information (such as activity data) collected through the GHGRP. Academic and research
16 centers also provide activity data and calculations to EPA, as well as individual companies participating in voluntary
17 outreach efforts with EPA. Finally, the U.S. Department of State officially submits the Inventory to the UNFCCC
18 each April. Figure 1-1 diagrams the National Inventory Arrangements.

1 **Figure 1-1: National Inventory Arrangements Diagram**

2

1.3 Inventory Process

This section describes EPA’s approach to preparing the annual U.S. Inventory, which consists of a National Inventory Report (NIR) and Common Reporting Format (CRF) tables. The inventory coordinator at EPA is responsible for compiling all emission estimates and ensuring consistency and quality throughout the NIR and CRF tables. Emission calculations for individual sources are the responsibility of individual source leads, who are most familiar with each source category and the unique characteristics of its emissions profile. The individual source leads determine the most appropriate methodology and collect the best activity data to use in the emission calculations, based upon their expertise in the source category, as well as coordinating with researchers and contractors familiar with the sources. A multi-stage process for collecting information from the individual source leads and producing the Inventory is undertaken annually to compile all information and data.

Methodology Development, Data Collection, and Emissions and Sink Estimation

Source leads at EPA collect input data and, as necessary, evaluate or develop the estimation methodology for the individual source categories. Because EPA has been preparing the Inventory for many years, for most source categories, the methodology for the previous year is applied to the new “current” year of the Inventory, and inventory analysts collect any new data or update data that have changed from the previous year. If estimates for a new source category are being developed for the first time, or if the methodology is changing for an existing source category (e.g., the United States is implementing a higher Tiered approach for that source category), then the source category lead will develop a new methodology, gather the most appropriate activity data and emission factors (or in some cases direct emission measurements) for the entire time series, and conduct a special source-specific review process involving relevant experts from industry, government, and universities.

Once the methodology is in place and the data are collected, the individual source leads calculate emissions and sink estimates. The source leads then update or create the relevant text and accompanying annexes for the Inventory. Source leads are also responsible for completing the relevant sectoral background tables of the CRF, conducting quality assurance and quality control (QA/QC) checks, and uncertainty analyses.

Summary Data Compilation and Storage

The inventory coordinator at EPA collects the source categories’ descriptive text and Annexes, and also aggregates the emission estimates into a summary spreadsheet that links the individual source category spreadsheets together. This summary sheet contains all of the essential data in one central location, in formats commonly used in the Inventory document. In addition to the data from each source category, national trend and related data are also gathered in the summary sheet for use in the Executive Summary, Introduction, and Recent Trends sections of the Inventory report. Electronic copies of each year’s summary spreadsheet, which contains all the emission and sink estimates for the United States, are kept on a central server at EPA under the jurisdiction of the inventory coordinator.

National Inventory Report Preparation

The NIR is compiled from the sections developed by each individual source lead. In addition, the inventory coordinator prepares a brief overview of each chapter that summarizes the emissions from all sources discussed in the chapters. The inventory coordinator then carries out a key category analysis for the Inventory, consistent with the *2006 IPCC Guidelines for National Greenhouse Gas Inventories*, and in accordance with the reporting requirements of the UNFCCC. Also at this time, the Introduction, Executive Summary, and Recent Trends sections are drafted, to reflect the trends for the most recent year of the current Inventory. The analysis of trends necessitates gathering supplemental data, including weather and temperature conditions, economic activity and gross domestic product, population, atmospheric conditions, and the annual consumption of electricity, energy, and fossil fuels. Changes in

1 these data are used to explain the trends observed in greenhouse gas emissions in the United States. Furthermore,
2 specific factors that affect individual sectors are researched and discussed. Many of the factors that affect emissions
3 are included in the Inventory document as separate analyses or side discussions in boxes within the text. Text boxes
4 are also created to examine the data aggregated in different ways than in the remainder of the document, such as a
5 focus on transportation activities or emissions from electricity generation. The document is prepared to match the
6 specification of the UNFCCC reporting guidelines for National Inventory Reports.

7 **Common Reporting Format Table Compilation**

8 The CRF tables are compiled from individual tables completed by each individual source lead, which contain source
9 emissions and activity data. The inventory coordinator integrates the source data into the UNFCCC’s “CRF
10 Reporter” for the United States, assuring consistency across all sectoral tables. The summary reports for emissions,
11 methods, and emission factors used, the overview tables for completeness and quality of estimates, the recalculation
12 tables, the notation key completion tables, and the emission trends tables are then completed by the inventory
13 coordinator. Internal automated quality checks on the CRF Reporter, as well as reviews by the source leads, are
14 completed for the entire time series of CRF tables before submission.

15 **QA/QC and Uncertainty**

16 QA/QC and uncertainty analyses are supervised by the QA/QC and uncertainty coordinators, who have general
17 oversight over the implementation of the QA/QC plan and the overall uncertainty analysis for the Inventory (see
18 sections on QA/QC and Uncertainty, below). These coordinators work closely with the source leads to ensure that a
19 consistent QA/QC plan and uncertainty analysis is implemented across all inventory sources. The inventory QA/QC
20 plan, detailed in a following section, is consistent with the quality assurance procedures outlined by EPA and IPCC.
21 The QA/QC and uncertainty findings also inform overall improvement planning, and specific improvements are
22 noted in the Planned Improvements sections of respective categories.

23 **Expert and Public Review Periods**

24 During the Expert Review period, a first draft of the document is sent to a select list of technical experts outside of
25 EPA. The purpose of the Expert Review is to encourage feedback on the methodological and data sources used in
26 the current Inventory, especially for sources which have experienced any changes since the previous Inventory.

27 Once comments are received and addressed, a second draft of the document is released for public review by
28 publishing a notice in the U.S. Federal Register and posting the document on the EPA Web site. The Public Review
29 period allows for a 30 day comment period and is open to the entire U.S. public. Comments may require further
30 discussion with experts or research, and specific Inventory improvements requiring further analysis as a result
31 comments are noted in categories Planned Improvement sections. See those sections for specific details.

32 **Final Submittal to UNFCCC and Document Printing**

33 After the final revisions to incorporate any comments from the Expert Review and Public Review periods, EPA
34 prepares the final National Inventory Report and the accompanying Common Reporting Format Reporter database.
35 The U.S. Department of State sends the official submission of the U.S. Inventory to the UNFCCC. The document is
36 then formatted and posted online, available for the public.¹

¹ See <<http://epa.gov/climatechange/ghgemissions/usinventoryreport.html>>.

1.4 Methodology and Data Sources

Emissions of greenhouse gases from various source and sink categories have been estimated using methodologies that are consistent with the *2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2006). To a great extent, this report makes use of published official economic and physical statistics for activity data and emission factors. Depending on the emission source category, activity data can include fuel consumption or deliveries, vehicle-miles traveled, raw material processed, etc. Emission factors are factors that relate quantities of emissions to an activity. For more information on data sources see Section 1.2 above, Box 1-1 on use of EPA's GHGRP data, Section 1.2 above and categories methodology sections for more information on data sources. In addition to official statistics, the report utilizes findings from academic studies, trade association surveys and statistical reports, along with expert judgement, consistent with 2006 IPCC Guidelines.

The IPCC methodologies provided in the *2006 IPCC Guidelines* represent foundational methodologies for a variety of source categories, and many of these methodologies continue to be improved and refined as new research and data become available. This report uses the IPCC methodologies when applicable, and supplements them with other available country-specific methodologies and data where possible. Choices made regarding the methodologies and data sources used are provided in conjunction with the discussion of each source category in the main body of the report. Complete documentation is provided in the annexes on the detailed methodologies and data sources utilized in the calculation of each source category.

Box 1-3: IPCC Reference Approach

The UNFCCC reporting guidelines require countries to complete a "top-down" reference approach for estimating CO₂ emissions from fossil fuel combustion in addition to their "bottom-up" sectoral methodology. This estimation method uses alternative methodologies and different data sources than those contained in that section of the Energy chapter. The reference approach estimates fossil fuel consumption by adjusting national aggregate fuel production data for imports, exports, and stock changes rather than relying on end-user consumption surveys (see Annex 4 of this report). The reference approach assumes that once carbon-based fuels are brought into a national economy, they are either saved in some way (e.g., stored in products, kept in fuel stocks, or left unoxidized in ash) or combusted, and therefore the carbon in them is oxidized and released into the atmosphere. Accounting for actual consumption of fuels at the sectoral or sub-national level is not required.

1.5 Key Categories

The *2006 IPCC Guidelines* (IPCC 2006) defines a key category as a "[category] that is prioritized within the national inventory system because its estimate has a significant influence on a country's total inventory of greenhouse gases in terms of the absolute level, the trend, or the uncertainty in emissions and removals."² By definition, key categories include those categories that have the greatest contribution to the absolute level of national emissions. In addition, when an entire time series of emission and removal estimates is prepared, a thorough investigation of key categories must also account for the influence of trends and uncertainties of individual source and sink categories. This analysis can identify source and sink categories that diverge from the overall trend in national emissions. Finally, a qualitative evaluation of key categories is performed to capture any categories that were not identified in any of the quantitative analyses.

Approach 1, as defined in the *2006 IPCC Guidelines* (IPCC 2006), was implemented to identify the key categories for the United States. This analysis was performed twice; one analysis included sources and sinks from the Land

² See Chapter 4 Volume 1, "Methodological Choice and Identification of Key Categories" in IPCC (2006). See <<http://www.ipcc-nggip.iges.or.jp/public/2006gl/index.html>>.

1 Use, Land-Use Change, and Forestry (LULUCF) sector, the other analysis did not include the LULUCF categories.
 2 Following Approach 1, Approach 2, as defined in the *2006 IPCC Guidelines* (IPCC 2006), was then implemented to
 3 identify any additional key categories not already identified in Approach 1 assessment. This analysis, which includes
 4 each source category’s uncertainty assessments (or proxies) in its calculations, was also performed twice to include
 5 or exclude LULUCF categories.

6 In addition to conducting Approach 1 and 2 level and trend assessments, a qualitative assessment of the source
 7 categories, as described in the *2006 IPCC Guidelines* (IPCC 2006), was conducted to capture any key categories that
 8 were not identified by either quantitative method. One additional key category, international bunker fuels, was
 9 identified using this qualitative assessment. International bunker fuels are fuels consumed for aviation or marine
 10 international transport activities, and emissions from these fuels are reported separately from totals in accordance
 11 with IPCC guidelines. If these emissions were included in the totals, bunker fuels would qualify as a key category
 12 according to Approach 1. The amount of uncertainty associated with estimation of emissions from international
 13 bunker fuels also supports the qualification of this source category as key, because it would qualify bunker fuels as a
 14 key category according to Approach 2. Table 1-4 presents the key categories for the United States (including and
 15 excluding LULUCF categories) using emissions and uncertainty data in this report, and ranked according to their
 16 sector and global warming potential (GWP)-weighted emissions in 2015. The table also indicates the criteria used in
 17 identifying these categories (i.e., level, trend, Approach 1, Approach 2, and/or qualitative assessments). Annex 1 of
 18 this report provides additional information regarding the key categories in the United States and the methodologies
 19 used to identify them.

20 **Table 1-4: Key Categories for the United States (1990-2015)**

IPCC Source Categories	Gas	Approach 1				Approach 2				Qual ^a	2015 Emissions (MMT CO ₂ Eq.)
		Level Without LULUCF	Trend Without LULUCF	Level With LULUCF	Trend With LULUCF	Level Without LULUCF	Trend Without LULUCF	Level With LULUCF	Trend With LULUCF

1.6 Quality Assurance and Quality Control (QA/QC)

As part of efforts to achieve its stated goals for inventory quality, transparency, and credibility, the United States has developed a quality assurance and quality control plan designed to check, document and improve the quality of its inventory over time. QA/QC activities on the Inventory are undertaken within the framework of the U.S. *Quality Assurance/Quality Control and Uncertainty Management Plan (QA/QC plan) for the U.S. Greenhouse Gas Inventory: Procedures Manual for QA/QC and Uncertainty Analysis*.

Key attributes of the QA/QC plan are summarized in Figure 1-2. These attributes include:

- *Procedures and Forms*: detailed and specific systems that serve to standardize the process of documenting and archiving information, as well as to guide the implementation of QA/QC and the analysis of uncertainty
- *Implementation of Procedures*: application of QA/QC procedures throughout the whole inventory development process from initial data collection, through preparation of the emission estimates, to publication of the Inventory
- *Quality Assurance*: expert and public reviews for both the Inventory estimates and the Inventory report (which is the primary vehicle for disseminating the results of the inventory development process). The expert technical review conducted by the UNFCCC supplements these QA processes, consistent with the *2006 IPCC Guidelines (IPCC 2006)*
- *Quality Control*: consideration of secondary data and category-specific checks (Tier 2 QC) in parallel and coordination with the uncertainty assessment; the development of protocols and templates, which provides for more structured communication and integration with the suppliers of secondary information
- *Tier 1 (general) and Tier 2 (category-specific) Checks*: quality controls and checks, as recommended by *IPCC Good Practice Guidance and 2006 IPCC Guidelines (IPCC 2006)*
- *Record Keeping*: provisions to track which procedures have been followed, the results of the QA/QC, uncertainty analysis, and feedback mechanisms for corrective action based on the results of the investigations which provide for continual data quality improvement and guided research efforts
- *Multi-Year Implementation*: a schedule for coordinating the application of QA/QC procedures across multiple years, especially for category-specific QC
- *Interaction and Coordination*: promoting communication within the EPA, across Federal agencies and departments, state government programs, and research institutions and consulting firms involved in supplying data or preparing estimates for the Inventory. The QA/QC Management Plan itself is intended to be revised and reflect new information that becomes available as the program develops, methods are improved, or additional supporting documents become necessary.

In addition, based on the national QA/QC plan for the Inventory, source-specific QA/QC plans have been developed for a number of sources. These plans follow the procedures outlined in the national QA/QC plan, tailoring the procedures to the specific text and spreadsheets of the individual sources. For each greenhouse gas emissions source or sink included in this Inventory, a minimum of a Tier 1 QA/QC analysis has been undertaken. Where QA/QC activities for a particular source go beyond the minimum Tier 1 level, and include category-specific checks (Tier 2)

1 further explanation is provided within the respective source category text. Similarly, responses or updates based on
 2 comments from the expert, public and the international technical expert reviews (e.g., UNFCCC) are also addressed
 3 within the respective source category text.

4 The quality control activities described in the U.S. QA/QC plan occur throughout the inventory process; QA/QC is
 5 not separate from, but is an integral part of, preparing the Inventory. Quality control—in the form of both good
 6 practices (such as documentation procedures) and checks on whether good practices and procedures are being
 7 followed—is applied at every stage of inventory development and document preparation. In addition, quality
 8 assurance occurs at two stages—an expert review and a public review. While both phases can significantly
 9 contribute to inventory quality, the public review phase is also essential for promoting the openness of the inventory
 10 development process and the transparency of the inventory data and methods.

11 The QA/QC plan guides the process of ensuring inventory quality by describing data and methodology checks,
 12 developing processes governing peer review and public comments, and developing guidance on conducting an
 13 analysis of the uncertainty surrounding the emission estimates. The QA/QC procedures also include feedback loops
 14 and provide for corrective actions that are designed to improve the inventory estimates over time.

15 **Figure 1-2: U.S. QA/QC Plan Summary**

16

17 1.7 Uncertainty Analysis of Emission Estimates

18 Uncertainty estimates are an essential element of a complete and transparent emissions inventory. Uncertainty
 19 information is not intended to dispute the validity of the Inventory estimates, but to help prioritize efforts to improve
 20 the accuracy of future Inventories and guide future decisions on methodological choice. While the U.S. Inventory

calculates its emission estimates with the highest possible accuracy, uncertainties are associated to a varying degree with the development of emission estimates for any inventory. Some of the current estimates, such as those for carbon dioxide (CO₂) emissions from energy-related activities, are considered to have minimal uncertainty associated with them. For some other categories of emissions, however, a lack of data or an incomplete understanding of how emissions are generated increases the uncertainty surrounding the estimates presented. The UNFCCC reporting guidelines follow the recommendation in the *2006 IPCC Guidelines* (IPCC 2006) and require that countries provide single point estimates for each gas and emission or removal source category. Within the discussion of each emission source, specific factors affecting the uncertainty associated with the estimates are discussed.

Additional research in the following areas could help reduce uncertainty in the U.S. Inventory:

- *Incorporating excluded emission sources.* Quantitative estimates for some of the sources and sinks of greenhouse gas emissions are not available at this time. In particular, emissions from some land-use activities and industrial processes are not included in the inventory either because data are incomplete or because methodologies do not exist for estimating emissions from these source categories. See Annex 5 of this report for a discussion of the sources of greenhouse gas emissions and sinks excluded from this report.
- *Improving the accuracy of emission factors.* Further research is needed in some cases to improve the accuracy of emission factors used to calculate emissions from a variety of sources. For example, the accuracy of current emission factors applied to CH₄ and N₂O emissions from stationary and mobile combustion is highly uncertain.
- *Collecting detailed activity data.* Although methodologies exist for estimating emissions for some sources, problems arise in obtaining activity data at a level of detail where more technology or process-specific emission factors can be applied.

The overall uncertainty estimate for total U.S. greenhouse gas emissions was developed using the IPCC Approach 2 uncertainty estimation methodology. Estimates of quantitative uncertainty for the total U.S. greenhouse gas emissions are shown below, in Table 1-5.

The IPCC provides good practice guidance on two approaches—Approach 1 and Approach 2—to estimating uncertainty for individual source categories. Approach 2 uncertainty analysis, employing the Monte Carlo Stochastic Simulation technique, was applied wherever data and resources permitted; further explanation is provided within the respective source category text and in Annex 7. Consistent with the *2006 IPCC Guidelines* (IPCC 2006), over a multi-year timeframe, the United States expects to continue to improve the uncertainty estimates presented in this report.

**Table 1-5: Estimated Overall Inventory Quantitative Uncertainty (MMT CO₂ Eq. and Percent)
— TO BE UPDATED FOR FINAL INVENTORY REPORT**

Gas	2014 Emission Estimate ^a (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^b				Mean ^c (MMT CO ₂ Eq.)	Standard Deviation ^c
		Lower Bound ^d (MMT CO ₂ Eq.)	Upper Bound ^d (MMT CO ₂ Eq.)	Lower Bound (%)	Upper Bound		
CO ₂	5,555.6	5,459.4	5,830.0	-2%	5%	5,643.8	94.9
CH ₄ ^e	730.8	674.3	917.5	-8%	26%	785.0	60.2
N ₂ O ^e	403.5	322.5	447.9	-20%	11%	378.6	32.2
PFC, HFC, SF ₆ , and NF ₃ ^e	175.3	172.3	190.9	-4%	6%	181.6	4.7
Total	6,865.2	6,765.4	7,223.9	-2%	5%	6,989.0	117.5
LULUCF Emissions^f	24.6	12.8	38.9	-48%	58%	23.0	6.8
LULUCF Total Net Flux^g	(787.0)	(1,051.4)	(647.8)	-18%	34%	(847.2)	102.9
LULUCF Sector Total^h	(762.5)	(1,029.8)	(622.5)	-18%	35%	(824.2)	103.0
Net Emissions (Sources and Sinks)	6,102.7	5,861.6	6,477.6	-4%	6%	6,164.8	156.7

Notes: Total emissions (excluding emissions for which uncertainty was not quantified) is presented without LULUCF. Net emissions is presented with LULUCF.

^a Emission estimates reported in this table correspond to emissions from only those source categories for which quantitative uncertainty was performed this year. Thus the totals reported in this table exclude approximately 5.3 MMT CO₂ Eq. of emissions for which quantitative uncertainty was not assessed. Hence, these emission estimates do not match the final total U.S. greenhouse gas emission estimates presented in this Inventory.

^b The lower and upper bounds for emission estimates correspond to a 95 percent confidence interval, with the lower bound corresponding to 2.5th percentile and the upper bound corresponding to 97.5th percentile.

^c Mean value indicates the arithmetic average of the simulated emission estimates; standard deviation indicates the extent of deviation of the simulated values from the mean.

^d The lower and upper bound emission estimates for the sub-source categories do not sum to total emissions because the low and high estimates for total emissions were calculated separately through simulations.

^e The overall uncertainty estimates did not take into account the uncertainty in the GWP values for CH₄, N₂O and high GWP gases used in the inventory emission calculations for 2014.

^f LULUCF emissions include the CO₂, CH₄, and N₂O emissions reported for Non-CO₂ Emissions from Forest Fires, N₂O Fluxes from Forest Soils, CO₂ Emissions from Agricultural Liming, CO₂ Emissions from Urea Fertilization, Peatlands Remaining Peatlands, and N₂O Fluxes from Settlement Soils.

^g Net CO₂ flux is the net C stock change from the following categories: Forest Land Remaining Forest Land, Land Converted to Forest Land, Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, Land Converted to Grassland, Settlements Remaining Settlements, and Other.

^h The LULUCF Sector Total is the net sum of all emissions (i.e., sources) of greenhouse gases to the atmosphere plus removals of CO₂ (i.e., sinks or negative emissions) from the atmosphere.

Notes: Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

1 Emissions calculated for the U.S. Inventory reflect current best estimates; in some cases, however, estimates are
2 based on approximate methodologies, assumptions, and incomplete data. As new information becomes available in
3 the future, the United States will continue to improve and revise its emission estimates. See Annex 7 of this report
4 for further details on the U.S. process for estimating uncertainty associated with the emission estimates and for a
5 more detailed discussion of the limitations of the current analysis and plans for improvement. Annex 7 also includes
6 details on the uncertainty analysis performed for selected source categories.

7 1.8 Completeness

8 This report, along with its accompanying CRF tables, serves as a thorough assessment of the anthropogenic sources
9 and sinks of greenhouse gas emissions for the United States for the time series 1990 through 2015. This report is
10 intended to be comprehensive and includes the vast majority of emissions and removals identified as anthropogenic,
11 consistent with IPCC and UNFCCC guidelines. Certain smaller sources have been identified which were excluded
12 from the estimates presented for various reasons. Generally speaking, sources not accounted for in this Inventory are
13 excluded due to data limitations and assessment of significance in terms of overall national emissions per UNFCCC
14 reporting guidelines. The United States is continually working to improve upon the understanding of such sources
15 and seeking to find the data required to estimate related emissions. As such improvements are implemented, new
16 emission sources are quantified and included in the Inventory. For a complete list of sources not included, see
17 Annex 5 of this report.

18 1.9 Organization of Report

19 In accordance with the revision of the UNFCCC reporting guidelines agreed to at the nineteenth Conference of the
20 Parties (UNFCCC 2014), this *Inventory of U.S. Greenhouse Gas Emissions and Sinks* is segregated into five sector-
21 specific chapters, listed below in Table 1-6. In addition, chapters on Trends in Greenhouse Gas Emissions and Other
22 information to be considered as part of the U.S. Inventory submission are included.

1 **Table 1-6: IPCC Sector Descriptions**

Chapter/IPCC Sector	Activities Included
Energy	Emissions of all greenhouse gases resulting from stationary and mobile energy activities including fuel combustion and fugitive fuel emissions, and non-energy use of fossil fuels.
Industrial Processes and Product Use	Emissions resulting from industrial processes and product use of greenhouse gases.
Agriculture	Anthropogenic emissions from agricultural activities except fuel combustion, which is addressed under Energy.
Land Use, Land-Use Change, and Forestry	Emissions and removals of CO ₂ , CH ₄ , and N ₂ O from forest management, other land-use activities, and land-use change.
Waste	Emissions from waste management activities.

2 Within each chapter, emissions are identified by the anthropogenic activity that is the source or sink of the
 3 greenhouse gas emissions being estimated (e.g., coal mining). Overall, the following organizational structure is
 4 consistently applied throughout this report:

5 **Chapter/IPCC Sector:** Overview of emission trends for each IPCC defined sector

6 **Source category:** Description of source pathway and emission trends.

7 **Methodology:** Description of analytical methods employed to produce emission estimates and identification of data
 8 references, primarily for activity data and emission factors.

9 **Uncertainty and Timeseries Consistency:** A discussion and quantification of the uncertainty in emission estimates
 10 and a discussion of time-series consistency.

11 **QA/QC and Verification:** A discussion on steps taken to QA/QC and verify the emission estimates, where beyond
 12 the overall U.S. QA/QC plan, and any key findings.

13 **Recalculations:** A discussion of any data or methodological changes that necessitate a recalculation of previous
 14 years' emission estimates, and the impact of the recalculation on the emission estimates, if applicable.

15 **Planned Improvements:** A discussion on any source-specific planned improvements, if applicable.

16 Special attention is given to CO₂ from fossil fuel combustion relative to other sources because of its share of
 17 emissions and its dominant influence on emission trends. For example, each energy consuming end-use sector (i.e.,
 18 residential, commercial, industrial, and transportation), as well as the electricity generation sector, is described
 19 individually. Additional information for certain source categories and other topics is also provided in several
 20 Annexes listed in Table 1-7.

21 **Table 1-7: List of Annexes**

ANNEX 1 Key Category Analysis
ANNEX 2 Methodology and Data for Estimating CO ₂ Emissions from Fossil Fuel Combustion

2. Trends in Greenhouse Gas Emissions

2.1 Recent Trends in U.S. Greenhouse Gas Emissions and Sinks

In 2015, total gross U.S. greenhouse gas emissions were 6,586.2 MMT or million metric tons carbon dioxide (CO₂) Eq. Total U.S. emissions have increased by 3.4 percent from 1990 to 2015, and emissions decreased from 2014 to 2015 by 2.2 percent (150.1 MMT CO₂ Eq.). The decrease in total greenhouse gas emissions between 2014 and 2015 was driven in large part by a decrease in CO₂ emissions from fossil fuel combustion. The decrease in CO₂ emissions from fossil fuel combustion was a result of multiple factors, including: (1) substitution from coal to natural gas consumption in the electric power sector; (2) warmer winter conditions in the first quarter of 2015 resulting in a decreased demand for heating fuel in the residential and commercial sectors; and (3) a slight decrease in electricity demand. Since 1990, U.S. emissions have increased at an average annual rate of 0.2 percent. Figure 2-1 through Figure 2-3 illustrate the overall trend in total U.S. emissions by gas, annual changes, and absolute changes since 1990. Overall, net emissions in 2015 were 11.2 percent below 2005 levels as shown in Table 2-1.

Figure 2-1: Gross U.S. Greenhouse Gas Emissions by Gas (MMT CO₂ Eq.)

1 **Figure 2-2: Annual Percent Change in Gross U.S. Greenhouse Gas Emissions Relative to the**
 2 **Previous Year**

3
 4
 5 **Figure 2-3: Cumulative Change in Annual Gross U.S. Greenhouse Gas Emissions Relative to**
 6 **1990 (1990=0, MMT CO₂ Eq.)**

7
 8 Overall, from 1990 to 2015, total emissions of CO₂ increased by 289.2 MMT CO₂ Eq. (5.6 percent), while total
 9 emissions of methane (CH₄) decreased by 131.2 MMT CO₂ Eq. (16.7 percent), and total emissions of nitrous oxide
 10 (N₂O) decreased by 24.5 MMT CO₂ Eq. (6.8 percent). During the same period, aggregate weighted emissions of
 11 hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), sulfur hexafluoride (SF₆), and nitrogen trifluoride (NF₃) rose
 12 by 85.9 MMT CO₂ Eq. (86.2 percent). Despite being emitted in smaller quantities relative to the other principal
 13 greenhouse gases, emissions of HFCs, PFCs, SF₆, and NF₃ are significant because many of them have extremely
 14 high global warming potentials (GWPs), and, in the cases of PFCs, SF₆, and NF₃, long atmospheric lifetimes.
 15 Conversely, U.S. greenhouse gas emissions were partly offset by carbon (C) sequestration in managed forests, trees
 16 in urban areas, agricultural soils, landfilled yard trimmings, and coastal wetlands. These were estimated to offset 5.9
 17 percent of total emissions in 2015.

18 As the largest contributor to U.S. greenhouse gas emissions, CO₂ from fossil fuel combustion has accounted for
 19 approximately 77 percent of GWP-weighted emissions for the entire time series since 1990. Emissions from this
 20 source category grew by 6.5 percent (308.5 MMT CO₂ Eq.) from 1990 to 2015 and were responsible for most of the
 21 increase in national emissions during this period. In addition, CO₂ emissions from fossil fuel combustion decreased

1 from 2005 levels by 698.0 MMT CO₂ Eq., a decrease of approximately 12.1 percent between 2005 to 2015. From
2 2014 to 2015, these emissions decreased by 2.9 percent (153.0 MMT CO₂ Eq.). Historically, changes in emissions
3 from fossil fuel combustion have been the dominant factor affecting U.S. emission trends.

4 Changes in CO₂ emissions from fossil fuel combustion are influenced by many long-term and short-term factors,
5 including population and economic growth, energy price fluctuations, technological changes, energy fuel choices,
6 and seasonal temperatures. On an annual basis, the overall consumption of fossil fuels in the United States fluctuates
7 primarily in response to changes in general economic conditions, energy prices, weather, and the availability of non-
8 fossil alternatives.

9 Energy-related CO₂ emissions also depend on the type of fuel or energy consumed and its C intensity. Producing a
10 unit of heat or electricity using natural gas instead of coal, for example, can reduce the CO₂ emissions because of the
11 lower C content of natural gas.

12 A brief discussion of the year to year variability in fuel combustion emissions is provided below, beginning with
13 2011.

14 From 2011 to 2012, CO₂ emissions from fossil fuel combustion decreased by 3.9 percent, with emissions from fossil
15 fuel combustion at their lowest level since 1994. This decrease from 2011 to 2012 is primarily a result of the
16 decrease in the carbon intensity of fuels used to generate electricity due to a slight increase in the price of coal, and a
17 significant decrease in the price of natural gas. The consumption of coal used to generate electricity decreased by
18 12.3 percent, while consumption of natural gas for electricity generation increased by 20.4 percent. Also, emissions
19 declined in the transportation sector largely due to a small increase in fuel efficiency across different transportation
20 modes and limited new demand for passenger transportation. In 2012, weather conditions remained fairly constant in
21 the summer and were much warmer in the winter compared to 2011, as cooling degree days increased by 1.7 percent
22 while heating degree days decreased 12.6 percent. This decrease in heating degree days resulted in a decreased
23 demand for heating fuel in the residential and commercial sector, which had a decrease in natural gas consumption
24 of 11.7 and 8.0 percent, respectively.

25 From 2012 to 2013, CO₂ emissions from fossil fuel combustion increased by 2.6 percent. This increase is primarily a
26 result of the increased energy consumption in the residential and commercial sectors, as heating degree days
27 increased 18.5 percent in 2013 as compared to 2012. The cooler weather led to an increase of 17.1 and 12.9 percent
28 direct use of fuels in the residential and commercial sectors, respectively. In addition, there was an increase of 1.5
29 and 0.8 percent in electricity consumption in the residential and commercial sectors, respectively, due to regions that
30 heat their homes with electricity. The consumption of natural gas used to generate electricity decreased by 9.8
31 percent due to an increase in the price of natural gas. Electric power plants shifted some consumption from natural
32 gas to coal, and as a result increased coal consumption to generate electricity by 4.0 percent. Lastly, industrial
33 production increased 1.9 percent from 2012 to 2013, resulting in an increase in the in CO₂ emissions from fossil fuel
34 combustion from the industrial sector by 3.7 percent.

35 From 2013 to 2014, CO₂ emissions from fossil fuel combustion increased by 0.9 percent. This increase is primarily a
36 result of the increased energy consumption in the transportation (approximately 40 percent of increase), residential
37 (approximately 35 percent of increase), and commercial (approximately 27 percent of increase) sectors. In the
38 transportation sector, VMT increased by 1.3 percent resulting in increased fuel consumption across on-road
39 transportation modes. Heating degree days increased 1.9 percent in 2014 as compared to 2013, resulting in an
40 increased demand in heating fuels for the residential and commercial sectors. The cooler weather led to an increase
41 of 4.6 and 4.9 percent in direct use of fuels in the residential and commercial sectors, respectively. In addition, there
42 was an increase of 0.9 and 1.1 percent in electricity consumption in the residential and commercial sectors,
43 respectively, due to regions that heat their homes with electricity. Lastly, industrial production increased 2.9 percent
44 from 2013 to 2014, resulting in a slight increase in CO₂ emissions from fossil fuel combustion from the industrial
45 sector by 0.4 percent. From the perspective of how these sector trends contributed to the overall 0.9 percent increase
46 from 2013 to 2014, the residential and commercial sectors were approximately 47 percent of the annual increase, the
47 transportation sector was 30 percent of the annual increase, and the industrial sector was just over 3 percent of the
48 2013 to 2014 increase in overall U.S. emissions.

49 From 2014 to 2015, CO₂ emissions from fossil fuel combustion decreased by 2.9 percent, with emissions from fossil
50 fuel combustion at their lowest level since 1995. This decrease from 2014 to 2015 is primarily a result of the
51 decrease in the carbon intensity of fuels used to generate electricity due to significant decrease in the price of natural
52 gas. The consumption of coal used to generate electricity decreased by 13.9 percent, while consumption of natural

1 gas for electricity generation increased by 18.7 percent. In 2015, weather conditions were much warmer in the
 2 summer and winter compared to 2014, as cooling degree days increased by 14.6 percent while heating degree days
 3 decreased 10.2 percent. This decrease in heating degree days resulted in a decreased demand for heating fuel in the
 4 residential and commercial sector, which had a decrease in natural gas consumption of 9.0 and 7.4 percent,
 5 respectively.

6 Table 2-1 summarizes emissions and sinks from all U.S. anthropogenic sources in weighted units of MMT CO₂ Eq.,
 7 while unweighted gas emissions and sinks in kilotons (kt) are provided in Table 2-2.

8 **Table 2-1: Recent Trends in U.S. Greenhouse Gas Emissions and Sinks (MMT CO₂ Eq.)**

Net Emissions (Sources and Sinks)	5,917.6	7,000.3	6,400.9	6,149.1	6,308.5	6,367.5	6,219.8

Notes: Total emissions presented without LULUCF. Net emissions presented with LULUCF.

+ Does not exceed 0.05 MMT CO₂ Eq.

^a Emissions from Wood Biomass and Ethanol Consumption are not included specifically in summing Energy sector totals. Net carbon fluxes from changes in biogenic carbon reservoirs are accounted for in the estimates for LULUCF.

^b Emissions from International Bunker Fuels are not included in totals.

^c Small amounts of PFC emissions also result from this source.

^d LULUCF emissions include the CO₂, CH₄, and N₂O emissions from *Peatlands Remaining Peatlands*; CH₄ and N₂O emissions reported for Non-CO₂ Emissions from Forest Fires, Non-CO₂ Emissions from Grassland Fires, and *Coastal Wetlands Remaining Coastal Wetlands*; CH₄ emissions from *Land Converted to Coastal Wetlands*; and N₂O Fluxes from Forest Soils and Settlement Soils.

^e Quality control uncovered errors in the estimate and uncertainty of soil C stock changes for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, and *Land Converted to Grassland* sections in the LULUCF chapter of this report.

^f LULUCF C Stock Change is the net C stock change from the following categories: *Forest Land Remaining Forest Land*, *Land Converted to Forest Land*, *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, *Land Converted to Grassland*, *Wetlands Remaining Wetlands*, *Land Converted to Wetlands*, *Settlements Remaining Settlements*, and *Land Converted to Settlements*. Refer to Table 2-8 for a breakout of emissions and removals for LULUCF by gas and source category.

^g The LULUCF Sector Net Total is the net sum of all emissions (i.e., sources) of greenhouse gases to the atmosphere plus removals of CO₂ (i.e., sinks or negative emissions) from the atmosphere.

Notes: Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

1 **Table 2-2: Recent Trends in U.S. Greenhouse Gas Emissions and Sinks (kt)**

M - Mixture of multiple gases

^a Emissions from Wood Biomass and Ethanol Consumption are not included specifically in summing Energy sector totals. Net carbon fluxes from changes in biogenic carbon reservoirs are accounted for in the estimates for LULUCF.

^b Emissions from International Bunker Fuels are not included in totals.

^c Small amounts of PFC emissions also result from this source.

Notes: Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

1 Emissions of all gases can be summed from each source category into a set of five sectors defined by the
 2 Intergovernmental Panel on Climate Change (IPCC). Figure 2-4 and Table 2-3 illustrate that over the twenty-six
 3 year period of 1990 to 2015, total emissions in the Energy, Industrial Processes and Product Use, and Agriculture
 4 sectors grew by 215.7 MMT CO₂ Eq. (4.0 percent), 36.7 MMT CO₂ Eq. (10.9 percent), and 27.0 MMT CO₂ Eq. (5.5
 5 percent), respectively. Emissions from the Waste sector decreased by 59.9 MMT CO₂ Eq. (30.1 percent). Over the
 6 same period, estimates of net C sequestration for the Land Use, Land-Use Change, and Forestry sector (magnitude
 7 of emissions plus CO₂ removals from all LULUCF categories) increased by 82.7 MMT CO₂ Eq. (18.4 percent).

Notes: Total emissions presented without LULUCF. Net emissions presented with LULUCF.

^a Total emissions without LULUCF.

^b Quality control uncovered errors in the estimate and uncertainty of soil C stock changes for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, and *Land Converted to Grassland* sections in the LULUCF chapter of this report.

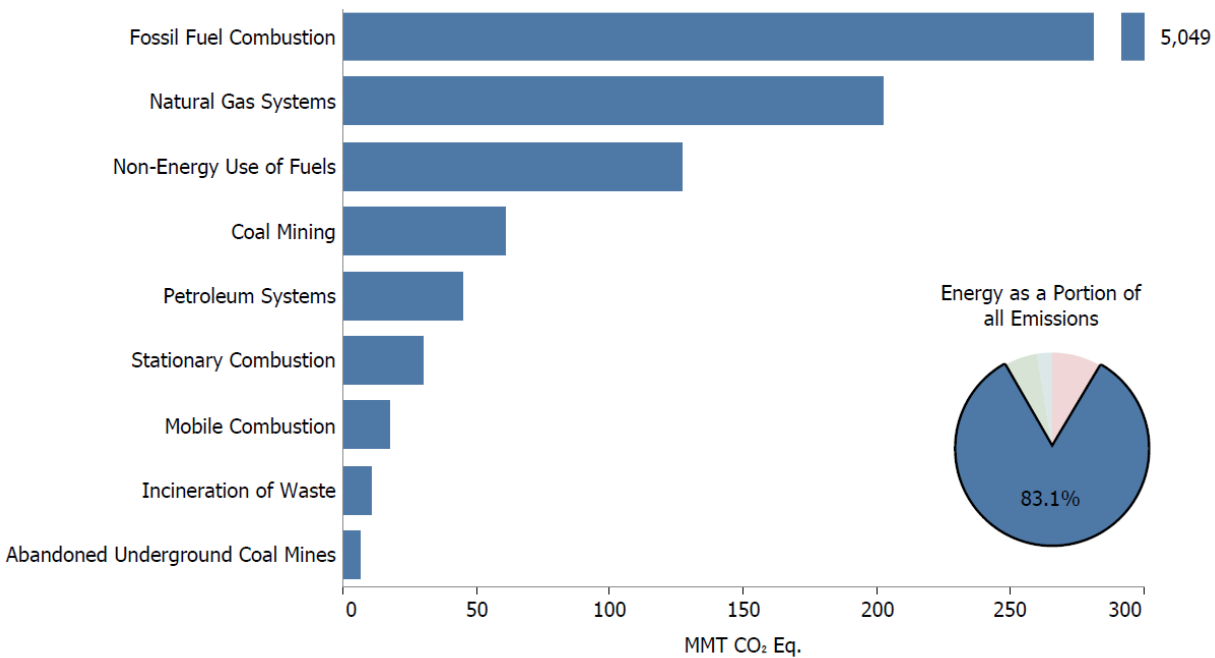

^c Net emissions with LULUCF.

Notes: Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

1 Energy

2 Energy-related activities, primarily fossil fuel combustion, accounted for the vast majority of U.S. CO₂ emissions for
3 the period of 1990 through 2015. In 2015, approximately 82 percent of the energy consumed in the United States (on
4 a Btu basis) was produced through the combustion of fossil fuels. The remaining 18 percent came from other energy
5 sources such as hydropower, biomass, nuclear, wind, and solar energy (see Figure 2-5 and Figure 2-6). A discussion
6 of specific trends related to CO₂ as well as other greenhouse gas emissions from energy consumption is presented in
7 the Energy chapter. Energy-related activities are also responsible for CH₄ and N₂O emissions (42 percent and 12
8 percent of total U.S. emissions of each gas, respectively). Table 2-4 presents greenhouse gas emissions from the
9 Energy chapter, by source and gas.

+ Does not exceed 0.05 MMT CO₂ Eq.

^aEmissions from Wood Biomass and Ethanol Consumption are not included specifically in summing energy sector totals. Net carbon fluxes from changes in biogenic carbon reservoirs are accounted for in the estimates for LULUCF.

^bEmissions from International Bunker Fuels are not included in totals.

Note: Totals may not sum due to independent rounding.

1
2 Carbon dioxide emissions from fossil fuel combustion are presented in Table 2-5 based on the underlying U.S.
3 energy consumer data collected by the U.S. Energy Information Administration (EIA). Estimates of CO₂ emissions
4 from fossil fuel combustion are calculated from these EIA “end-use sectors” based on total consumption and
5 appropriate fuel properties (any additional analysis and refinement of the EIA data is further explained in the Energy
6 chapter of this report). EIA’s fuel consumption data for the electric power sector are comprised of electricity-only
7 and combined-heat-and-power (CHP) plants within the North American Industry Classification System (NAICS) 22
8 category whose primary business is to sell electricity, or electricity and heat, to the public (nonutility power
9 producers can be included in this sector as long as they meet they electric power sector definition). EIA statistics for
10 the industrial sector include fossil fuel consumption that occurs in the fields of manufacturing, agriculture, mining,
11 and construction. EIA’s fuel consumption data for the transportation sector consists of all vehicles whose primary
12 purpose is transporting people and/or goods from one physical location to another. EIA’s fuel consumption data for
13 the industrial sector consists of all facilities and equipment used for producing, processing, or assembling goods
14 (EIA includes generators that produce electricity and/or useful thermal output primarily to support on-site industrial
15 activities in this sector). EIA’s fuel consumption data for the residential sector consist of living quarters for private
16 households. EIA’s fuel consumption data for the commercial sector consist of service-providing facilities and
17 equipment from private and public organizations and businesses (EIA includes generators that produce electricity
18 and/or useful thermal output primarily to support the activities at commercial establishments in this sector). Table
19 2-5 and Figure 2-7 summarize CO₂ emissions from fossil fuel combustion by end-use sector. Figure 2-8 further
20 describes the total emissions from fossil fuel combustion, separated by end-use sector, including CH₄ and N₂O in
21 addition to CO₂.

22 **Table 2-5: CO₂ Emissions from Fossil Fuel Combustion by End-Use Sector (MMT CO₂ Eq.)**

End-Use Sector	1990	2005	2011	2012	2013	2014	2015

5
6

5 **Figure 2-8: 2015 End-Use Sector Emissions of CO₂ from Fossil Fuel Combustion (MMT CO₂**
 6 **Eq.)**

7
8

9 The main driver of emissions in the Energy sector is CO₂ from fossil fuel combustion. Electricity generation is the
 10 largest emitter of CO₂, and electricity generators consumed 34 percent of U.S. energy from fossil fuels and emitted
 11 38 percent of the CO₂ from fossil fuel combustion in 2015. Electricity generation emissions can also be allocated to
 12 the end-use sectors that are consuming that electricity, as presented in Table 2-5. The transportation end-use sector
 13 accounted for 1,737.0 MMT CO₂ Eq. in 2015 or approximately 34 percent of total CO₂ emissions from fossil fuel
 14 combustion. The industrial end-use sector accounted for 27 percent of CO₂ emissions from fossil fuel
 15 combustion. The residential and commercial end-use sectors accounted for 20 and 18 percent, respectively, of CO₂ emissions
 16 from fossil fuel combustion. Both of these end-use sectors were heavily reliant on electricity for meeting energy
 17 needs, with electricity consumption for lighting, heating, air conditioning, and operating appliances contributing 68
 18 and 75 percent of emissions from the residential and commercial end-use sectors, respectively. Significant trends in
 19 emissions from energy source categories over the twenty six-year period from 1990 through 2015 included the
 20 following:

- 21 • Total CO₂ emissions from fossil fuel combustion increased from 4,740.7 MMT CO₂ Eq. in 1990 to 5,049.2
 22 MMT CO₂ Eq. in 2015 – a 6.5 percent total increase over the twenty six-year period. From 2014 to 2015,
 23 these emissions decreased by 153.0 MMT CO₂ Eq. (2.9 percent).

- 1 • Methane emissions from natural gas systems and petroleum systems (combined here) decreased from 254.8
2 MMT CO₂ Eq. in 1990 to 201.5 MMT CO₂ Eq. (53.3 MMT CO₂ Eq. or 20.9 percent) from 1990 to 2015.
3 Natural gas systems CH₄ emissions decreased by 36.5 MMT CO₂ Eq. (18.6 percent) since 1990, largely due
4 to a decrease in emissions from transmission, storage, and distribution. The decrease in transmission and
5 storage emissions is largely due to reduced compressor station emissions (including emissions from
6 compressors and fugitives). The decrease in distribution emissions is largely attributed to increased use of
7 plastic piping, which has lower emissions than other pipe materials, and station upgrades at metering and
8 regulating (M&R) stations. Petroleum systems CH₄ emissions decreased by 16.8 MMT CO₂ Eq. (or 28.8
9 percent) since 1990. This decrease is due primarily to decreases in emissions from associated gas venting.
- 10 • Carbon dioxide emissions from non-energy uses of fossil fuels increased by 9.4 MMT CO₂ Eq. (8.0
11 percent) from 1990 through 2015. Emissions from non-energy uses of fossil fuels were 127.0 MMT CO₂
12 Eq. in 2015, which constituted 2.3 percent of total national CO₂ emissions, approximately the same
13 proportion as in 1990.
- 14 • Nitrous oxide emissions from stationary combustion increased by 11.2 MMT CO₂ Eq. (94.0 percent) from
15 1990 through 2015. Nitrous oxide emissions from this source increased primarily as a result of an increase
16 in the number of coal fluidized bed boilers in the electric power sector.
- 17 • Nitrous oxide emissions from mobile combustion decreased by 25.8 MMT CO₂ Eq. (62.7 percent) from
18 1990 through 2015, primarily as a result of N₂O national emission control standards and emission control
19 technologies for on-road vehicles.
- 20 • Carbon dioxide emissions from incineration of waste (10.7 MMT CO₂ Eq. in 2015) increased by 2.7 MMT
21 CO₂ Eq. (34.3 percent) from 1990 through 2015, as the volume of plastics and other fossil carbon-
22 containing materials in municipal solid waste grew.

23 The decrease in CO₂ emissions from fossil fuel combustion was a result of multiple factors, including: (1)
24 substitution from coal to natural gas consumption in the electric power sector; (2) warmer winter conditions in the
25 first quarter of 2015 resulting in a decreased demand for heating fuel in the residential and commercial sectors; and
26 (3) a slight decrease in electricity demand.

27 Industrial Processes and Product Use

28 The Industrial Processes and Product Use (IPPU) chapter includes greenhouse gas emissions occurring from
29 industrial processes and from the use of greenhouse gases in products.

30 Greenhouse gas emissions are produced as the by-products of many non-energy-related industrial activities. For
31 example, industrial processes can chemically transform raw materials, which often release waste gases such as CO₂,
32 CH₄, and N₂O. These processes include iron and steel production and metallurgical coke production, cement
33 production, ammonia production, urea consumption, lime production, other process uses of carbonates (e.g., flux
34 stone, flue gas desulfurization, and glass manufacturing), soda ash production and consumption, titanium dioxide
35 production, phosphoric acid production, ferroalloy production, CO₂ consumption, silicon carbide production and
36 consumption, aluminum production, petrochemical production, nitric acid production, adipic acid production, lead
37 production, zinc production, and N₂O from product uses (see Figure 2-9). Industrial processes also release HFCs,
38 PFCs, SF₆, and NF₃ and other fluorinated compounds. In addition to the use of HFCs and some PFCs as substitutes
39 for ozone depleting substances (ODS), fluorinated compounds such as HFCs, PFCs, SF₆, NF₃, and others are
40 employed and emitted by a number of other industrial sources in the United States. These industries include
41 aluminum production, HCFC-22 production, semiconductor manufacture, electric power transmission and
42 distribution, and magnesium metal production and processing. Table 2-6 presents greenhouse gas emissions from
43 industrial processes by source category.

+ Does not exceed 0.05 MMT CO₂ Eq.

^a Small amounts of PFC emissions also result from this source.

Note: Totals may not sum due to independent rounding.

- 1 Overall, emissions from the IPPU sector increased by 10.9 percent from 1990 to 2015. Significant trends in
2 emissions from IPPU source categories over the twenty six-year period from 1990 through 2015 included the
3 following:
- 4 • Hydrofluorocarbon emissions from ODS substitutes have been increasing from small amounts in 1990 to
5 168.6 MMT CO₂ Eq. in 2015. This increase was in large part the result of efforts to phase out
6 chlorofluorocarbons (CFCs) and other ODSs in the United States. In the short term, this trend is expected to
7 continue, and will likely continue over the next decade as hydrochlorofluorocarbons (HCFCs), which are
8 interim substitutes in many applications, are themselves phased-out under the provisions of the
9 Copenhagen Amendments to the Montreal Protocol.
 - 10 • Combined CO₂ and CH₄ emissions from iron and steel production and metallurgical coke production
11 decreased by 16.7 percent to 47.9 MMT CO₂ Eq. from 2014 to 2015, and have declined overall by 51.8
12 MMT CO₂ Eq. (51.9 percent) from 1990 through 2015, due to restructuring of the industry, technological
13 improvements, and increased scrap steel utilization.
 - 14 • Carbon dioxide emissions from ammonia production (10.8 MMT CO₂ Eq. in 2015) decreased by 2.2 MMT
15 CO₂ Eq. (17.2 percent) since 1990. Ammonia production relies on natural gas as both a feedstock and a
16 fuel, and as such, market fluctuations and volatility in natural gas prices affect the production of ammonia.
 - 17 • Urea consumption for non-agricultural purposes (1.1 MMT CO₂ Eq. in 2015) decreased by 2.7 MMT CO₂
18 Eq. (70.2 percent) since 1990. From 1990 to 2007, emissions increased by 31 percent to a peak of 4.9
19 MMT CO₂ Eq., before decreasing by 77 percent to 2015 levels.

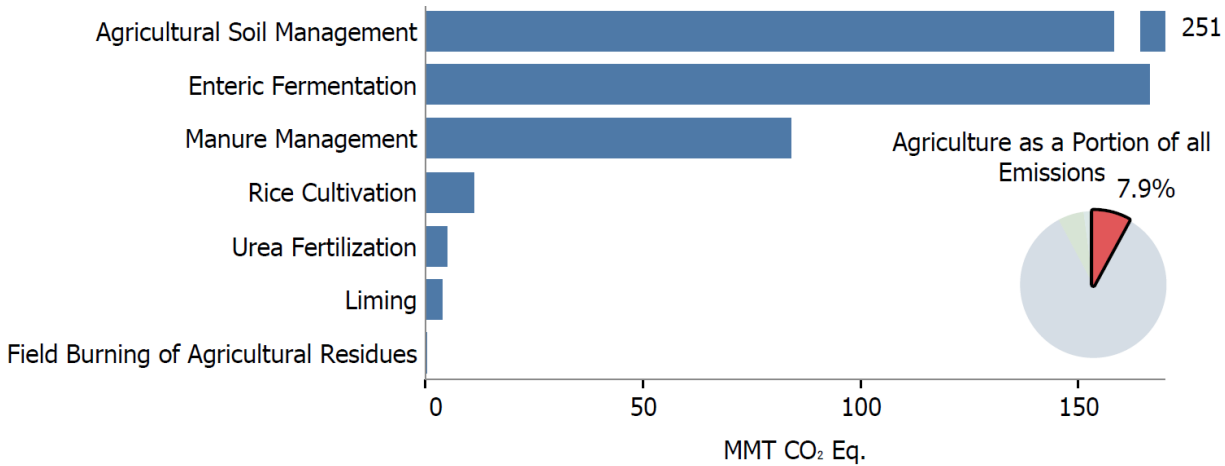

- 1 • In 2015, N₂O emissions from product uses constituted 1.3 percent of U.S. N₂O emissions. From 1990 to
2 2015, emissions from this source category decreased by 0.4 percent, though slight increases occurred in
3 intermediate years.
- 4 • Nitrous oxide emissions from adipic acid production were 4.3 MMT CO₂ Eq. in 2015, and have decreased
5 significantly since 1990 due to both the widespread installation of pollution control measures in the late
6 1990s and plant idling in the late 2000s. Emissions from adipic acid production have decreased by 72.0
7 percent since 1990 and by 74.8 percent since a peak in 1995.
- 8 • PFC emissions from aluminum production decreased by 90.7 percent (19.5 MMT CO₂ Eq.) from 1990 to
9 2015, due to both industry emission reduction efforts and lower domestic aluminum production.

10 Agriculture

11 Agricultural activities contribute directly to emissions of greenhouse gases through a variety of processes, including
12 the following source categories: enteric fermentation in domestic livestock, livestock manure management, rice
13 cultivation, agricultural soil management, liming, urea fertilization, and field burning of agricultural residues.

14 In 2015, agricultural activities were responsible for emissions of 522.3 MMT CO₂ Eq., or 7.9 percent of total U.S.
15 greenhouse gas emissions. Carbon dioxide, methane and nitrous oxide were the primary greenhouse gases emitted
16 by agricultural activities. Carbon dioxide emissions from the application of crushed limestone and dolomite (i.e., soil
17 liming) and urea fertilization represented 0.2 percent of total CO₂ emissions from anthropogenic activities. Methane
18 emissions from enteric fermentation and manure management represented approximately 25.4 percent and 10.1
19 percent of total CH₄ emissions from anthropogenic activities, respectively, in 2015. Agricultural soil management
20 activities, such as fertilizer use and other cropping practices, were the largest source of U.S. N₂O emissions in 2015,
21 accounting for 75.0 percent. Figure 2-10 and Table 2-7 illustrate agricultural greenhouse gas emissions by source.

22 **Figure 2-10: 2015 Agriculture Chapter Greenhouse Gas Sources (MMT CO₂ Eq.)**

23
24

1 **Table 2-7: Emissions from Agriculture (MMT CO₂ Eq.)**

Gas/Source	1990	2005	2011	2012	2013	2014	2015
CO₂	7.1	7.9	8.0	10.2	8.4	8.4	8.8

Total	495.3	526.4	541.9	525.9	516.9	514.7	522.3

Note: Totals may not sum due to independent rounding.

2 Some significant trends in U.S. emissions from Agriculture source categories include the following:

- 3 • Agricultural soils produced approximately 75.0 percent of N₂O emissions in the United States in 2015. Estimated emissions from this source in 2015 were 251.3 MMT CO₂ Eq. Annual N₂O emissions from agricultural soils fluctuated between 1990 and 2015, although overall emissions were 2.0 percent lower in 2015 than in 1990. Year-to-year fluctuations are largely a reflection of annual variation in weather patterns, synthetic fertilizer use, and crop production.
- 8 • Enteric fermentation is the largest anthropogenic source of CH₄ emissions in the United States. In 2015, enteric fermentation CH₄ emissions were 166.5 MMT CO₂ Eq. (25.4 percent of total CH₄ emissions), which represents an increase of 2.4 MMT CO₂ Eq. (1.5 percent) since 1990. This increase in emissions from 1990 to 2015 in enteric fermentation generally follows the increasing trends in cattle populations. From 1990 to 1995, emissions increased and then generally decreased from 1996 to 2004, mainly due to fluctuations in beef cattle populations and increased digestibility of feed for feedlot cattle. Emissions increased from 2005 to 2007, as both dairy and beef populations increased. Research indicates that the feed digestibility of dairy cow diets decreased during this period. Emissions decreased again from 2008 to 2015 as beef cattle populations again decreased.
- 17 • Liming and urea fertilization are the only source of CO₂ emissions from Agriculture. Estimated emissions from these sources were 3.8 and 5.0 MMT CO₂ Eq., respectively. Liming and urea fertilization emissions increased by 5.6 percent and 5.3 percent, respectively, relative to 2014, and decreased by 18.4 percent and increased by 108.2 percent, respectively since 1990.
- 21 • Overall, emissions from manure management increased 64.2 percent between 1990 and 2015. This encompassed an increase of 78.3 percent for CH₄, from 37.2 MMT CO₂ Eq. in 1990 to 66.3 MMT CO₂ Eq. in 2015; and an increase of 26.6 percent for N₂O, from 14.0 MMT CO₂ Eq. in 1990 to 17.7 MMT CO₂ Eq. in 2015. The majority of the increase observed in CH₄ resulted from swine and dairy cow manure, where emissions increased 58 and 136 percent, respectively, from 1990 to 2015. From 2014 to 2015, there was a 5.4 percent increase in total CH₄ emissions from manure management, mainly due to minor shifts in the animal populations and the resultant effects on manure management system allocations.

28 Land Use, Land-Use Change, and Forestry

29 When humans alter the terrestrial biosphere through land use, changes in land use, and land management practices, they also alter the background C fluxes between biomass, soils, and the atmosphere. Overall, managed land is a net sink for CO₂ (C sequestration) in the United States. The drivers of fluxes on managed lands include, for example,

1 forest management practices, tree planting in urban areas, the management of agricultural soils, the landfilling of
2 yard trimmings and food scraps, and activities that cause changes in C stocks in coastal wetlands. The main drivers
3 for net forest sequestration include net forest growth, increasing forest area, and a net accumulation of carbon stocks
4 in harvested wood pools. The net sequestration in *Settlements Remaining Settlements*, which occurs predominantly
5 from urban forests and landfilled yard trimmings and food scraps, is a result of net tree growth and increased urban
6 forest size, as well as long-term accumulation of yard trimmings and food scraps carbon in landfills.

7 *Forest Land Remaining Forest Land* (including vegetation, soils, and harvested wood) represented the largest
8 carbon sink from LULUCF, accounting for 77 percent of total 2015 negative C fluxes; *Settlements Remaining*
9 *Settlements* (urban trees and landfilled yard trimmings and food scraps) accounted for 12 percent; *Land Converted to*
10 *Forest Land* accounted for 9 percent; and *Cropland Remaining Cropland*, *Wetlands Remaining Wetlands*, and *Land*
11 *Converted to Wetlands* accounted for 3 percent of the total negative C fluxes in 2015. Conversely, *Land Converted*
12 *to Grassland* represented the largest carbon source from LULUCF, accounting for 61 percent of total 2015 positive
13 C fluxes, while *Land Converted to Settlements* accounted for 31 percent. *Land Converted to Cropland* accounted for
14 6 percent. *Grassland Remaining Grassland* accounted for 2 percent, and settlement soils in *Settlements Remaining*
15 *Settlements* accounted for less than 0.5 percent of the total positive C fluxes in 2015. Overall, positive C fluxes
16 totaled 481.6 MMT CO₂ Eq. in 2015, while negative C fluxes totaled 868.5 MMT CO₂ Eq. in 2015.

17 The LULUCF sector in 2015 resulted in a net increase in C stocks (i.e., net CO₂ removals) of 386.8 MMT CO₂ Eq.
18 (Table 2-3).¹ This represents an offset of approximately 5.9 percent of total (i.e., gross) greenhouse gas emissions in
19 2015. Emissions from LULUCF activities in 2015 are 20.4 MMT CO₂ Eq. and represent 0.3 percent of total
20 greenhouse gas emissions.² Between 1990 and 2015, total C sequestration in the LULUCF sector decreased by 16.0
21 percent, primarily due to a decrease in the rate of net C accumulation in forests and an increase in emissions from
22 *Land Converted to Grassland*.³

23 Carbon dioxide removals are presented in Table 2-8 along with CO₂, CH₄, and N₂O emissions for LULUCF source
24 categories. Lands undergoing peat extraction (i.e., *Peatlands Remaining Peatlands*) resulted in CO₂ emissions of 0.8
25 MMT CO₂ Eq. (763 kt of CO₂). Forest fires were the largest source of CH₄ emissions from LULUCF in 2015,
26 totaling 7.3 MMT CO₂ Eq. (292 kt of CH₄). *Coastal Wetlands Remaining Coastal Wetlands* resulted in CH₄
27 emissions of 3.5 MMT CO₂ Eq. (141 kt of CH₄). Grassland fires resulted in CH₄ emissions of 0.4 MMT CO₂ Eq. (16
28 kt of CH₄). *Peatlands Remaining Peatlands* and *Land Converted to Wetlands* resulted in CH₄ emissions of less than
29 0.05 MMT CO₂ Eq.

30 Forest fires were also the largest source of N₂O emissions from LULUCF in 2015, totaling 4.8 MMT CO₂ Eq. (16 kt
31 of N₂O). Nitrous oxide emissions from fertilizer application to settlement soils in 2015 totaled to 2.6 MMT CO₂ Eq.
32 (9 kt of N₂O). This represents an increase of 81.5 percent since 1990. Additionally, the application of synthetic
33 fertilizers to forest soils in 2015 resulted in N₂O emissions of 0.5 MMT CO₂ Eq. (2 kt of N₂O). Nitrous oxide
34 emissions from fertilizer application to forest soils have increased by 455 percent since 1990, but still account for a
35 relatively small portion of overall emissions. Grassland fires resulted in N₂O emissions of 0.4 MMT CO₂ Eq. (1 kt
36 of N₂O). *Coastal Wetlands Remaining Coastal Wetlands* resulted in N₂O emissions of 0.1 MMT CO₂ Eq. (0.5 kt of
37 N₂O), and *Peatlands Remaining Peatlands* resulted in N₂O emissions of less than 0.05 MMT CO₂ Eq. (see Table
38 2-8).

¹ LULUCF C Stock Change is the net C stock change from the following categories: *Forest Land Remaining Forest Land*, *Land Converted to Forest Land*, *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, *Land Converted to Grassland*, *Wetlands Remaining Wetlands*, *Land Converted to Wetlands*, *Settlements Remaining Settlements*, and *Land Converted to Settlements*.

² LULUCF emissions include the CO₂, CH₄, and N₂O emissions from *Peatlands Remaining Peatlands*; CH₄ and N₂O emissions reported for Non-CO₂ Emissions from Forest Fires, Non-CO₂ Emissions from Grassland Fires, and *Coastal Wetlands Remaining Coastal Wetlands*; CH₄ emissions from *Land Converted to Coastal Wetlands*; and N₂O Fluxes from Forest Soils and Settlement Soils.

³ Quality control uncovered errors in the estimate and uncertainty of soil C stock changes for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, and *Land Converted to Grassland* sections in the LULUCF chapter of this report.

+ Absolute value does not exceed 0.05 MMT CO₂ Eq.

^a LULUCF C Stock Change is the net C stock change from the following categories: *Forest Land Remaining Forest Land, Land Converted to Forest Land, Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, Land Converted to Grassland, Wetlands Remaining Wetlands, Land Converted to Wetlands, Settlements Remaining Settlements, and Land Converted to Settlements.*

^b Includes the effects of net additions to stocks of carbon stored in forest ecosystem pools and harvested wood products.

^c Quality control uncovered errors in the estimate and uncertainty of soil C stock changes for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, and Land Converted to Grassland* sections in the LULUCF chapter of this report.

^d Estimates include emissions from N fertilizer additions on both *Settlements Remaining Settlements* and *Land Converted to Settlements.*

^e Estimates include emissions from N fertilizer additions on both *Forest Land Remaining Forest Land* and *Land Converted to Forest Land.*

^f LULUCF emissions include the CO₂, CH₄, and N₂O emissions from *Peatlands Remaining Peatlands*; CH₄ and N₂O emissions reported for *Non-CO₂ Emissions from Forest Fires, Non-CO₂ Emissions from Grassland Fires, and Coastal*

Wetlands Remaining Coastal Wetlands; CH₄ emissions from *Land Converted to Coastal Wetlands*; and N₂O Fluxes from Forest Soils and Settlement Soils.

^g The LULUCF Sector Net Total is the net sum of all emissions (i.e., sources) of greenhouse gases to the atmosphere plus removals of CO₂ (i.e., sinks or negative emissions) from the atmosphere.

Notes: Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

1 Other significant trends from 1990 to 2015 in emissions from LULUCF categories include:

- 2 • Annual C sequestration by forest land (i.e., annual C stock accumulation in the five C pools for *Forest*
3 *Land Remaining Forest Land* and *Land Converted to Forest Land*) has decreased by approximately 6
4 percent since 1990. This is primarily due to decreased carbon sequestration from forest carbon stocks.
- 5 • Annual C sequestration from *Settlements Remaining Settlements* (which includes urban trees and landfilled
6 yard trimmings and food scraps) has increased by 18.4 percent over the period from 1990 to 2015. This is
7 primarily due to an increase in urbanized land area in the United States.
- 8 • Annual emissions from *Land Converted to Grassland* increased by approximately 20 percent from 1990 to
9 2015 due to losses in aboveground biomass, belowground biomass, dead wood, and litter C stocks from
10 *Forest Land Converted to Grassland*.
- 11 • Annual emissions from *Land Converted to Settlements* increased by approximately 21 percent from 1990 to
12 2015 due to losses in aboveground biomass C stocks from *Forest Land Converted to Settlements* and
13 mineral soils C stocks from *Grassland Converted to Settlements*.

14 Waste

15 Waste management and treatment activities are sources of greenhouse gas emissions (see Figure 2-11). In 2015,
16 landfills were the third-largest source of U.S. anthropogenic CH₄ emissions, accounting for 17.7 percent of total
17 U.S. CH₄ emissions.⁴ Additionally, wastewater treatment accounts for 14.2 percent of Waste emissions, 2.3 percent
18 of U.S. CH₄ emissions, and 1.5 percent of N₂O emissions. Emissions of CH₄ and N₂O from composting grew from
19 1990 to 2015, and resulted in emissions of 4.0 MMT CO₂ Eq. in 2015. A summary of greenhouse gas emissions
20 from the Waste chapter is presented in Table 2-9.

21

22 **Figure 2-11: 2015 Waste Chapter Greenhouse Gas Sources (MMT CO₂ Eq.)**

23

⁴ Landfills also store carbon, due to incomplete degradation of organic materials such as wood products and yard trimmings, as described in the Land Use, Land-Use Change, and Forestry chapter.

1
 2 Overall, in 2015, waste activities generated emissions of 139.4 MMT CO₂ Eq., or 2.1 percent of total U.S.
 3 greenhouse gas emissions.

4 **Table 2-9: Emissions from Waste (MMT CO₂ Eq.)**

Gas/Source	1990	2005	2011	2012	2013	2014	2015
CH₄	195.6	152.1	136.2	137.9	133.7	133.5	132.6
Landfills	179.6	134.3	119.0	120.8	116.7	116.6	115.7
Wastewater Treatment	15.7	16.0	15.3	15.1	14.9	14.8	14.8
Composting	0.4	1.9	1.9	1.9	2.0	2.1	2.1
N₂O	3.7	6.1	6.4	6.6	6.7	6.8	6.9
Wastewater Treatment	3.4	4.4	4.8	4.8	4.9	4.9	5.0
Composting	0.3	1.7	1.7	1.7	1.8	1.9	1.9
Total	199.3	158.2	142.6	144.4	140.4	140.2	139.4

Note: Totals may not sum due to independent rounding.

5 Some significant trends in U.S. emissions from waste source categories include the following:

- 6 • From 1990 to 2015, net CH₄ emissions from landfills decreased by 63.8 MMT CO₂ Eq. (35.6 percent), with
 7 small increases occurring in interim years. This downward trend in emissions coincided with increased
 8 landfill gas collection and control systems, and a reduction of decomposable materials (i.e., paper and
 9 paperboard, food scraps, and yard trimmings) discarded in MSW landfills over the time series.
- 10 • Combined CH₄ and N₂O emissions from composting have generally increased since 1990, from 0.7 MMT
 11 CO₂ Eq. to 4.0 MMT CO₂ Eq. in 2015, which represents slightly more than a five-fold increase over the
 12 time series. The growth in composting since the 1990s is attributable to primarily two factors: (1) steady
 13 growth in population and residential housing, and (2) the enactment of legislation by state and local
 14 governments that discouraged the disposal of yard trimmings in landfills.
- 15 • From 1990 to 2015, CH₄ and N₂O emissions from wastewater treatment decreased by 0.9 MMT CO₂ Eq.
 16 (5.8 percent) and increased by 1.6 MMT CO₂ Eq. (47.0 percent), respectively. Methane emissions from
 17 domestic wastewater treatment have decreased since 1999 due to decreasing percentages of wastewater
 18 being treated in anaerobic systems, including reduced use of on-site septic systems and central anaerobic
 19 treatment systems. Nitrous oxide emissions from wastewater treatment processes gradually increased
 20 across the time series as a result of increasing U.S. population and protein consumption.

21 2.2 Emissions by Economic Sector

22 Throughout this report, emission estimates are grouped into five sectors (i.e., chapters) defined by the IPCC and
 23 detailed above: Energy; Industrial Processes and Product Use; Agriculture; LULUCF; and Waste. While it is
 24 important to use this characterization for consistency with UNFCCC reporting guidelines, it is also useful to
 25 characterize emissions according to commonly used economic sector categories: residential, commercial, industry,
 26 transportation, electricity generation, and agriculture, as well as U.S. Territories.

27 Using this categorization, emissions from electricity generation accounted for the largest portion (29 percent) of
 28 total U.S. greenhouse gas emissions in 2015. Transportation activities, in aggregate, accounted for the second largest
 29 portion (27 percent). Emissions from industry accounted for about 22 percent of total U.S. greenhouse gas emissions
 30 in 2015. Emissions from industry have in general declined over the past decade due to a number of factors, including
 31 structural changes in the U.S. economy (i.e., shifts from a manufacturing-based to a service-based economy), fuel
 32 switching, and efficiency improvements. The remaining 21 percent of U.S. greenhouse gas emissions were
 33 contributed by the residential, agriculture, and commercial sectors, plus emissions from U.S. Territories. The
 34 residential sector accounted for 6 percent, and primarily consisted of CO₂ emissions from fossil fuel combustion.
 35 Activities related to agriculture accounted for roughly 9 percent of U.S. emissions; unlike other economic sectors,
 36 agricultural sector emissions were dominated by N₂O emissions from agricultural soil management and CH₄

1 emissions from enteric fermentation, rather than CO₂ from fossil fuel combustion. The commercial sector accounted
 2 for roughly 6 percent of emissions, while U.S. Territories accounted for less than 1 percent. Carbon dioxide was also
 3 emitted and sequestered (in the form of C) by a variety of activities related to forest management practices, tree
 4 planting in urban areas, the management of agricultural soils, landfilling of yard trimmings, and changes in C stocks
 5 in coastal wetlands.

6 Table 2-10 presents a detailed breakdown of emissions from each of these economic sectors by source category, as
 7 they are defined in this report. Figure 2-12 shows the trend in emissions by sector from 1990 to 2015.

Net Emissions (Sources and Sinks)	5,917.6	7,000.3	6,400.9	6,149.1	6,308.5	6,367.5	6,219.8	94.4%

Note: Total emissions presented without LULUCF. Total net emissions presented with LULUCF.

+ Does not exceed 0.05 MMT CO₂ Eq. or 0.05 percent.

^a Percent of total (gross) emissions excluding emissions from LULUCF for 2015.

^b The LULUCF Sector Net Total is the net sum of all emissions (i.e., sources) of greenhouse gases to the atmosphere plus removals of CO₂ (i.e., sinks or negative emissions) from the atmosphere.

^c Quality control uncovered errors in the estimate and uncertainty of soil C stock changes for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, and *Land Converted to Grassland* sections in the LULUCF chapter of this report.

Notes: Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

1 Emissions with Electricity Distributed to Economic Sectors

2 It can also be useful to view greenhouse gas emissions from economic sectors with emissions related to electricity
3 generation distributed into end-use categories (i.e., emissions from electricity generation are allocated to the
4 economic sectors in which the electricity is consumed). The generation, transmission, and distribution of electricity,
5 which is the largest economic sector in the United States, accounted for 29 percent of total U.S. greenhouse gas
6 emissions in 2015. Emissions increased by 4 percent since 1990, as electricity demand grew and fossil fuels
7 remained the dominant energy source for generation. Electricity generation-related emissions decreased from 2014
8 to 2015 by 6.7 percent, primarily due to decreased CO₂ emissions from fossil fuel combustion due to an increase in
9 natural gas consumption, and decreased coal consumption. Electricity sales to the residential and commercial end-
10 use sectors in 2015 decreased by 0.2 percent and increased by 0.6 percent, respectively. The trend in the residential
11 and commercial sectors can largely be attributed to warmer, less energy-intensive winter conditions compared to
12 2014. Electricity sales to the industrial sector in 2015 decreased by approximately 1.1 percent. Overall, in 2015, the
13 amount of electricity generated (in kWh) decreased by 0.2 percent from the previous year. This decrease in
14 generation contributed to a reduction in CO₂ emissions from the electric power sector of 6.7 percent, as the
15 consumption of CO₂-intensive coal for electricity generation decreased by 13.9 percent and natural gas generation
16 increased by 18.7 percent. The consumption of petroleum for electricity generation decreased by 6.6 percent in 2015
17 relative to 2014. Table 2-11 provides a detailed summary of emissions from electricity generation-related activities.

18 **Table 2-11: Electricity Generation-Related Greenhouse Gas Emissions (MMT CO₂ Eq.)**

Gas/Fuel Type or Source	1990	2005	2011	2012	2013	2014	2015

--------------	----------------	----------------	----------------	----------------	----------------	----------------	----------------

+ Does not exceed 0.05 MMT CO₂ Eq.

^a Includes only stationary combustion emissions related to the generation of electricity.

Note: Totals may not sum due to independent rounding.

1 To distribute electricity emissions among economic end-use sectors, emissions from the source categories assigned
 2 to the electricity generation sector were allocated to the residential, commercial, industry, transportation, and
 3 agriculture economic sectors according to each economic sector's share of retail sales of electricity consumption
 4 (EIA 2016 and Duffield 2006). These source categories include CO₂ from Fossil Fuel Combustion, CH₄ and N₂O
 5 from Stationary Combustion, Incineration of Waste, Other Process Uses of Carbonates, and SF₆ from Electrical
 6 Transmission and Distribution Systems. Note that only 50 percent of the Other Process Uses of Carbonates
 7 emissions were associated with electricity generation and distributed as described; the remainder of Other Process
 8 Uses of Carbonates emissions were attributed to the industrial processes economic end-use sector.⁵

9 When emissions from electricity are distributed among these sectors, industrial activities account for the largest
 10 share of total U.S. greenhouse gas emissions (29.7 percent), followed closely by emissions from transportation (27.4
 11 percent). Emissions from the residential and commercial sectors also increase substantially when emissions from
 12 electricity are included. In all sectors except agriculture, CO₂ accounts for more than 80 percent of greenhouse gas
 13 emissions, primarily from the combustion of fossil fuels.

14 Table 2-12 presents a detailed breakdown of emissions from each of these economic sectors, with emissions from
 15 electricity generation distributed to them. Figure 2-13 shows the trend in these emissions by sector from 1990 to
 16 2015.

17 **Figure 2-13: U.S. Greenhouse Gas Emissions with Electricity-Related Emissions Distributed**
 18 **to Economic Sectors (MMT CO₂ Eq.)**

19
20

⁵ Emissions were not distributed to U.S. Territories, since the electricity generation sector only includes emissions related to the generation of electricity in the 50 states and the District of Columbia.

Note: Total emissions presented without LULUCF. Net emissions presented with LULUCF.

+ Does not exceed 0.05 MMT CO₂ Eq. or 0.05 percent.

^a Percent of total gross emissions excluding emissions from LULUCF for year 2015.

^b Includes primarily HFC-134a.

^c The LULUCF Sector Net Total is the net sum of all emissions (i.e., sources) of greenhouse gases to the atmosphere plus removals of CO₂ (i.e., sinks or negative emissions) from the atmosphere.

^d Quality control uncovered errors in the estimate and uncertainty of soil C stock changes for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, and *Land Converted to Grassland* sections in the LULUCF chapter of this report.

Notes: Emissions from electricity generation are allocated based on aggregate electricity consumption in each end-use sector. Totals may not sum due to independent rounding.

1 Industry

2 The industry end-use sector includes CO₂ emissions from fossil fuel combustion from all manufacturing facilities, in
3 aggregate. This end-use sector also includes emissions that are produced as a byproduct of the non-energy-related
4 industrial process activities. The variety of activities producing these non-energy-related emissions includes CH₄
5 emissions from petroleum and natural gas systems, fugitive CH₄ emissions from coal mining, by-product CO₂
6 emissions from cement manufacture, and HFC, PFC, SF₆, and NF₃ byproduct emissions from semiconductor
7 manufacture, to name a few. Since 1990, industrial sector emissions have declined. The decline has occurred both in
8 direct emissions and indirect emissions associated with electricity use. In theory, emissions from the industrial end-
9 use sector should be highly correlated with economic growth and industrial output, but heating of industrial
10 buildings and agricultural energy consumption are also affected by weather conditions. In addition, structural
11 changes within the U.S. economy that lead to shifts in industrial output away from energy-intensive manufacturing
12 products to less energy-intensive products (e.g., from steel to computer equipment) also have a significant effect on
13 industrial emissions.

14 Transportation

15 When electricity-related emissions are distributed to economic end-use sectors, transportation activities accounted
16 for 27 percent of U.S. greenhouse gas emissions in 2015. The largest sources of transportation greenhouse gases in
17 2015 were passenger cars (41.5 percent), freight trucks (23.0 percent), light-duty trucks, which include sport utility
18 vehicles, pickup trucks, and minivans (18.3 percent), commercial aircraft (6.6 percent), rail (2.5 percent), other
19 aircraft (2.2 percent), pipelines (2.1 percent), and ships and boats (1.8 percent). These figures include direct CO₂,
20 CH₄, and N₂O emissions from fossil fuel combustion used in transportation and emissions from non-energy use (i.e.,
21 lubricants) used in transportation, as well as HFC emissions from mobile air conditioners and refrigerated transport
22 allocated to these vehicle types.

23 In terms of the overall trend, from 1990 to 2015, total transportation emissions rose by 16 percent due, in large part,
24 to increased demand for travel as fleet wide light-duty vehicle fuel economy was relatively stable (average new
25 vehicle fuel economy declined slowly from 1990 through 2004 and then increased more rapidly from 2005 through
26 2015). The number of vehicle miles traveled by light-duty motor vehicles (passenger cars and light-duty trucks)
27 increased 42 percent from 1990 to 2015,⁶ as a result of a confluence of factors including population growth,
28 economic growth, urban sprawl, and periods of low fuel prices. The decline in new light-duty vehicle fuel economy
29 between 1990 and 2004 reflected the increasing market share of light-duty trucks, which grew from about 30 percent

⁶ VMT estimates are based on data from FHWA Highway Statistics Table VM-1 (FHWA 1996 through 2016). Table VM-1 data for 2015 have not been published yet, therefore 2015 mileage data is estimated using the 3.5 percent increase in FHWA Traffic Volume Trends from 2014 to 2015.

of new vehicle sales in 1990 to 48 percent in 2004. Starting in 2005, the rate of VMT growth slowed while average new vehicle fuel economy began to increase. Average new vehicle fuel economy has improved almost every year since 2005, and the truck share has decreased to about 43 percent of new vehicles in Model Year (MY) 2015 (EPA 2016a). Table 2-13 provides a detailed summary of greenhouse gas emissions from transportation-related activities with electricity-related emissions included in the totals. It is important to note that there was a change in methods between 2014 and 2015 used to estimate gasoline consumption in the transportation sector. In the absence of this change, CO₂ emissions from passenger cars, light-duty trucks, and other on-road vehicles using gasoline would likely have been higher in 2015.⁷

From 2008 to 2009, CO₂ emissions from the transportation end-use sector declined 4.2 percent. The decrease in emissions could largely be attributed to decreased economic activity in 2009 and an associated decline in the demand for transportation. Modes such as medium- and heavy-duty trucks were significantly impacted by the decline in freight transport. After reaching a decadal low in 2012, CO₂ emissions from the transportation end-use sector stabilized as the economic recovery gained strength.

Almost all of the energy consumed for transportation was supplied by petroleum-based products, with more than half being related to gasoline consumption in automobiles and other highway vehicles. Other fuel uses, especially diesel fuel for freight trucks and jet fuel for aircraft, accounted for the remainder. The primary driver of transportation-related emissions was CO₂ from fossil fuel combustion, which increased by 16 percent from 1990 to 2015. This rise in CO₂ emissions, combined with an increase in HFCs from close to zero emissions in 1990 to 45.1 MMT CO₂ Eq. in 2015, led to an increase in overall emissions from transportation activities of 16 percent.

Table 2-13: Transportation-Related Greenhouse Gas Emissions (MMT CO₂ Eq.)

Gas/Vehicle	1990	2005	2011	2012	2013	2014	2015

⁷ In 2016, FHWA changed its methods for estimating the share of motor gasoline used in on-highway and off-highway applications. This resulted in an increase in the estimated off-highway motor gasoline consumption and subsequent decrease in the on-highway motor gasoline consumption for 2015.

+ Does not exceed 0.05 MMT CO₂ Eq.

^a Consists of emissions from jet fuel consumed by domestic operations of commercial aircraft (no bunkers).

^b Consists of emissions from jet fuel and aviation gasoline consumption by general aviation and military aircraft.

^c Fluctuations in emission estimates are associated with fluctuations in reported fuel consumption, and may reflect issues with data sources.

^d Other emissions from electricity generation are a result of waste incineration (as the majority of municipal solid waste is combusted in “trash-to-steam” electricity generation plants), electrical transmission and distribution, and a portion of Other Process Uses of Carbonates (from pollution control equipment installed in electricity generation plants).

^e CO₂ estimates reflect natural gas used to power pipelines, but not electricity. While the operation of pipelines produces CH₄ and N₂O, these emissions are not directly attributed to pipelines in the U.S. Inventory.

^f Emissions from International Bunker Fuels include emissions from both civilian and military activities; these emissions are not included in the transportation totals.

Notes: Passenger cars and light-duty trucks include vehicles typically used for personal travel and less than 8,500 lbs; medium- and heavy-duty trucks include vehicles larger than 8,500 lbs. HFC emissions primarily reflect HFC-134a. Totals may not sum due to independent rounding.

1 Commercial

2 The commercial sector is heavily reliant on electricity for meeting energy needs, with electricity consumption for
3 lighting, heating, air conditioning, and operating appliances. The remaining emissions were largely due to the direct
4 consumption of natural gas and petroleum products, primarily for heating and cooking needs. Energy-related
5 emissions from the residential and commercial sectors have generally been increasing since 1990, and are often
6 correlated with short-term fluctuations in energy consumption caused by weather conditions, rather than prevailing
7 economic conditions. Landfills and wastewater treatment are included in this sector, with landfill emissions
8 decreasing since 1990 and wastewater treatment emissions decreasing slightly.

9 Residential

10 The residential sector is heavily reliant on electricity for meeting energy needs, with electricity consumption for
11 lighting, heating, air conditioning, and operating appliances. The remaining emissions were largely due to the direct
12 consumption of natural gas and petroleum products, primarily for heating and cooking needs. Emissions from the
13 residential sectors have generally been increasing since 1990, and are often correlated with short-term fluctuations in

1 energy consumption caused by weather conditions, rather than prevailing economic conditions. In the long-term, this
2 sector is also affected by population growth, regional migration trends, and changes in housing and building
3 attributes (e.g., size and insulation).

4 **Agriculture**

5 The agriculture end-use sector includes a variety of processes, including enteric fermentation in domestic livestock,
6 livestock manure management, and agricultural soil management. In 2015, agricultural soil management was the
7 largest source of N₂O emissions, and enteric fermentation was the largest source of CH₄ emissions in the United
8 States. This sector also includes small amounts of CO₂ emissions from fossil fuel combustion by motorized farm
9 equipment like tractors. The agriculture sector is less reliant on electricity than the other sectors.

10

11 **Box 2-1: Methodology for Aggregating Emissions by Economic Sector**

12 In presenting the Economic Sectors in the annual *Inventory of U.S. Greenhouse Gas Emissions and Sinks*, the
13 Inventory expands upon the standard IPCC sectors common for UNFCCC reporting. Discussing greenhouse gas
14 emissions relevant to U.S.-specific sectors improves communication of the report’s findings.

15 In the Electricity Generation economic sector, CO₂ emissions from the combustion of fossil fuels included in the
16 EIA electric utility fuel consuming sector are apportioned to this economic sector. Stationary combustion emissions
17 of CH₄ and N₂O are also based on the EIA electric utility sector. Additional sources include CO₂, CH₄, and N₂O
18 from waste incineration, as the majority of municipal solid waste is combusted in “trash-to-steam” electricity
19 generation plants. The Electricity Generation economic sector also includes SF₆ from Electrical Transmission and
20 Distribution, and a portion of CO₂ from Other Process Uses of Carbonates (from pollution control equipment
21 installed in electricity generation plants).

22 In the Transportation economic sector, the CO₂ emissions from the combustion of fossil fuels included in the EIA
23 transportation fuel consuming sector are apportioned to this economic sector (additional analyses and refinement of
24 the EIA data is further explained in the Energy chapter of this report). Emissions of CH₄ and N₂O from Mobile
25 Combustion are also apportioned to this economic sector based on the EIA transportation fuel consuming sector.
26 Substitution of Ozone Depleting Substances emissions are apportioned based on their specific end-uses within the
27 source category, with emissions from transportation refrigeration/air-conditioning systems to this economic sector.
28 Finally, CO₂ emissions from Non-Energy Uses of Fossil Fuels identified as lubricants for transportation vehicles are
29 included in the Transportation economic sector.

30 For the Industry economic sector, the CO₂ emissions from the combustion of fossil fuels included in the EIA
31 industrial fuel consuming sector, minus the agricultural use of fuel explained below, are apportioned to this
32 economic sector. The CH₄ and N₂O emissions from stationary and mobile combustion are also apportioned to this
33 economic sector based on the EIA industrial fuel consuming sector, minus emissions apportioned to the Agriculture
34 economic sector described below. Substitution of Ozone Depleting Substances emissions are apportioned based on
35 their specific end-uses within the source category, with most emissions falling within the Industry economic sector.
36 Additionally, all process-related emissions from sources with methods considered within the IPCC IPPU sector have
37 been apportioned to this economic sector. This includes the process-related emissions (i.e., emissions from the actual
38 process to make the material, not from fuels to power the plant) from such activities as Cement Production, Iron and
39 Steel Production and Metallurgical Coke Production, and Ammonia Production. Additionally, fugitive emissions
40 from energy production sources, such as Natural Gas Systems, Coal Mining, and Petroleum Systems are included in
41 the Industry economic sector. A portion of CO₂ from Other Process Uses of Carbonates (from pollution control
42 equipment installed in large industrial facilities) are also included in the Industry economic sector. Finally, all
43 remaining CO₂ emissions from Non-Energy Uses of Fossil Fuels are assumed to be industrial in nature (besides the
44 lubricants for transportation vehicles specified above), and are attributed to the Industry economic sector.

45 As agriculture equipment is included in EIA’s industrial fuel consuming sector surveys, additional data is used to
46 extract the fuel used by agricultural equipment, to allow for accurate reporting in the Agriculture economic sector
47 from all sources of emissions, such as motorized farming equipment. Energy consumption estimates are obtained
48 from Department of Agriculture survey data, in combination with separate EIA fuel sales reports. This
49 supplementary data is used to apportion some of the CO₂ emissions from fossil fuel combustion, and CH₄ and N₂O

1 emissions from stationary and mobile combustion, to the Agriculture economic sector. The other emission sources
 2 included in this economic sector are intuitive for the agriculture sectors, such as N₂O emissions from Agricultural
 3 Soils, CH₄ from Enteric Fermentation, CH₄ and N₂O from Manure Management, CH₄ from Rice Cultivation, CO₂
 4 emissions from Liming and Urea Application, and CH₄ and N₂O from Forest Fires. Nitrous oxide emissions from
 5 the Application of Fertilizers to tree plantations (termed “forest land” by the IPCC) are also included in the
 6 Agriculture economic sector.

7 The Residential economic sector includes the CO₂ emissions from the combustion of fossil fuels reported for the
 8 EIA residential sector. Stationary combustion emissions of CH₄ and N₂O are also based on the EIA residential fuel
 9 consuming sector. Substitution of Ozone Depleting Substances are apportioned based on their specific end-uses
 10 within the source category, with emissions from residential air-conditioning systems to this economic sector. Nitrous
 11 oxide emissions from the Application of Fertilizers to developed land (termed “settlements” by the IPCC) are also
 12 included in the Residential economic sector.

13 The Commercial economic sector includes the CO₂ emissions from the combustion of fossil fuels reported in the
 14 EIA commercial fuel consuming sector data. Emissions of CH₄ and N₂O from Mobile Combustion are also
 15 apportioned to this economic sector based on the EIA transportation fuel consuming sector. Substitution of Ozone
 16 Depleting Substances emissions are apportioned based on their specific end-uses within the source category, with
 17 emissions from commercial refrigeration/air-conditioning systems apportioned to this economic sector. Public works
 18 sources including direct CH₄ from Landfills and CH₄ and N₂O from Wastewater Treatment and Composting are also
 19 included in this economic sector.

20

Box 2-2: Recent Trends in Various U.S. Greenhouse Gas Emissions-Related Data

22 Total emissions can be compared to other economic and social indices to highlight changes over time. These
 23 comparisons include: (1) emissions per unit of aggregate energy consumption, because energy-related activities are
 24 the largest sources of emissions; (2) emissions per unit of fossil fuel consumption, because almost all energy-related
 25 emissions involve the combustion of fossil fuels; (3) emissions per unit of electricity consumption, because the
 26 electric power industry—utilities and non-utilities combined—was the largest source of U.S. greenhouse gas
 27 emissions in 2015; (4) emissions per unit of total gross domestic product as a measure of national economic activity;
 28 or (5) emissions per capita.

29 Table 2-14 provides data on various statistics related to U.S. greenhouse gas emissions normalized to 1990 as a
 30 baseline year. Greenhouse gas emissions in the United States have grown at an average annual rate of 0.2 percent
 31 since 1990. Since 1990, this rate is slightly slower than that for total energy and for fossil fuel consumption, and
 32 much slower than that for electricity consumption, overall gross domestic product and national population (see
 33 Table 2-14 and Figure 2-14).

34 **Table 2-14: Recent Trends in Various U.S. Data (Index 1990 = 100)**

6 2.3 Indirect Greenhouse Gas Emissions (CO, 7 NO_x, NMVOCs, and SO₂)

8 The reporting requirements of the UNFCCC⁸ request that information be provided on indirect greenhouse gases,
 9 which include CO, NO_x, NMVOCs, and SO₂. These gases do not have a direct global warming effect, but indirectly
 10 affect terrestrial radiation absorption by influencing the formation and destruction of tropospheric and stratospheric
 11 ozone, or, in the case of SO₂, by affecting the absorptive characteristics of the atmosphere. Additionally, some of
 12 these gases may react with other chemical compounds in the atmosphere to form compounds that are greenhouse
 13 gases. Carbon monoxide is produced when carbon-containing fuels are combusted incompletely. Nitrogen oxides
 14 (i.e., NO and NO₂) are created by lightning, fires, fossil fuel combustion, and in the stratosphere from N₂O. Non-
 15 methane volatile organic compounds—which include hundreds of organic compounds that participate in
 16 atmospheric chemical reactions (i.e., propane, butane, xylene, toluene, ethane, and many others)—are emitted
 17 primarily from transportation, industrial processes, and non-industrial consumption of organic solvents. In the
 18 United States, SO₂ is primarily emitted from coal combustion for electric power generation and the metals industry.
 19 Sulfur-containing compounds emitted into the atmosphere tend to exert a negative radiative forcing (i.e., cooling)
 20 and therefore are discussed separately.

21 One important indirect climate change effect of NMVOCs and NO_x is their role as precursors for tropospheric ozone
 22 formation. They can also alter the atmospheric lifetimes of other greenhouse gases. Another example of indirect
 23 greenhouse gas formation into greenhouse gases is the interaction of CO with the hydroxyl radical—the major

⁸ See <<http://unfccc.int/resource/docs/2013/cop19/eng/10a03.pdf>>.

1 atmospheric sink for CH₄ emissions—to form CO₂. Therefore, increased atmospheric concentrations of CO limit the
 2 number of hydroxyl molecules (OH) available to destroy CH₄.

3 Since 1970, the United States has published estimates of emissions of CO, NO_x, NMVOCs, and SO₂ (EPA 2015),⁹
 4 which are regulated under the Clean Air Act. Table 2-15 shows that fuel combustion accounts for the majority of
 5 emissions of these indirect greenhouse gases. Industrial processes—such as the manufacture of chemical and allied
 6 products, metals processing, and industrial uses of solvents—are also significant sources of CO, NO_x, and
 7 NMVOCs.

8 **Table 2-15: Emissions of NO_x, CO, NMVOCs, and SO₂ (kt)**

Box 2-3: Sources and Effects of Sulfur Dioxide

Sulfur dioxide (SO₂) emitted into the atmosphere through natural and anthropogenic processes affects the earth's radiative budget through its photochemical transformation into sulfate aerosols that can (1) scatter radiation from the sun back to space, thereby reducing the radiation reaching the earth's surface; (2) affect cloud formation; and (3) affect atmospheric chemical composition (e.g., by providing surfaces for heterogeneous chemical reactions). The indirect effect of sulfur-derived aerosols on radiative forcing can be considered in two parts. The first indirect effect is the aerosols' tendency to decrease water droplet size and increase water droplet concentration in the atmosphere. The second indirect effect is the tendency of the reduction in cloud droplet size to affect precipitation by increasing cloud lifetime and thickness. Although still highly uncertain, the radiative forcing estimates from both the first and the second indirect effect are believed to be negative, as is the combined radiative forcing of the two (IPCC 2001). However, because SO₂ is short-lived and unevenly distributed in the atmosphere, its radiative forcing impacts are highly uncertain.

Sulfur dioxide is also a major contributor to the formation of regional haze, which can cause significant increases in acute and chronic respiratory diseases. Once SO₂ is emitted, it is chemically transformed in the atmosphere and returns to the earth as the primary source of acid rain. Because of these harmful effects, the United States has regulated SO₂ emissions in the Clean Air Act.

Electricity generation is the largest anthropogenic source of SO₂ emissions in the United States, accounting for 59.2 percent in 2012. Coal combustion contributes nearly all of those emissions (approximately 92 percent). Sulfur dioxide emissions have decreased in recent years, primarily as a result of electric power generators switching from high-sulfur to low-sulfur coal and installing flue gas desulfurization equipment.

3. Energy

Energy-related activities were the primary sources of U.S. anthropogenic greenhouse gas emissions, accounting for 84.3 percent of total greenhouse gas emissions on a carbon dioxide (CO₂) equivalent basis in 2015.¹ This included 97, 42, and 12 percent of the nation's CO₂, methane (CH₄), and nitrous oxide (N₂O) emissions, respectively. Energy-related CO₂ emissions alone constituted 79.5 percent of national emissions from all sources on a CO₂ equivalent basis, while the non-CO₂ emissions from energy-related activities represented a much smaller portion of total national emissions (4.8 percent collectively).

Emissions from fossil fuel combustion comprise the vast majority of energy-related emissions, with CO₂ being the primary gas emitted (see Figure 3-1). Globally, approximately 32,381 million metric tons (MMT) of CO₂ were added to the atmosphere through the combustion of fossil fuels in 2014, of which the United States accounted for approximately 16 percent.² Due to their relative importance, fossil fuel combustion-related CO₂ emissions are considered separately, and in more detail than other energy-related emissions (see Figure 3-2). Fossil fuel combustion also emits CH₄ and N₂O. Stationary combustion of fossil fuels was the second largest source of N₂O emissions in the United States and mobile fossil fuel combustion was the fourth largest source.

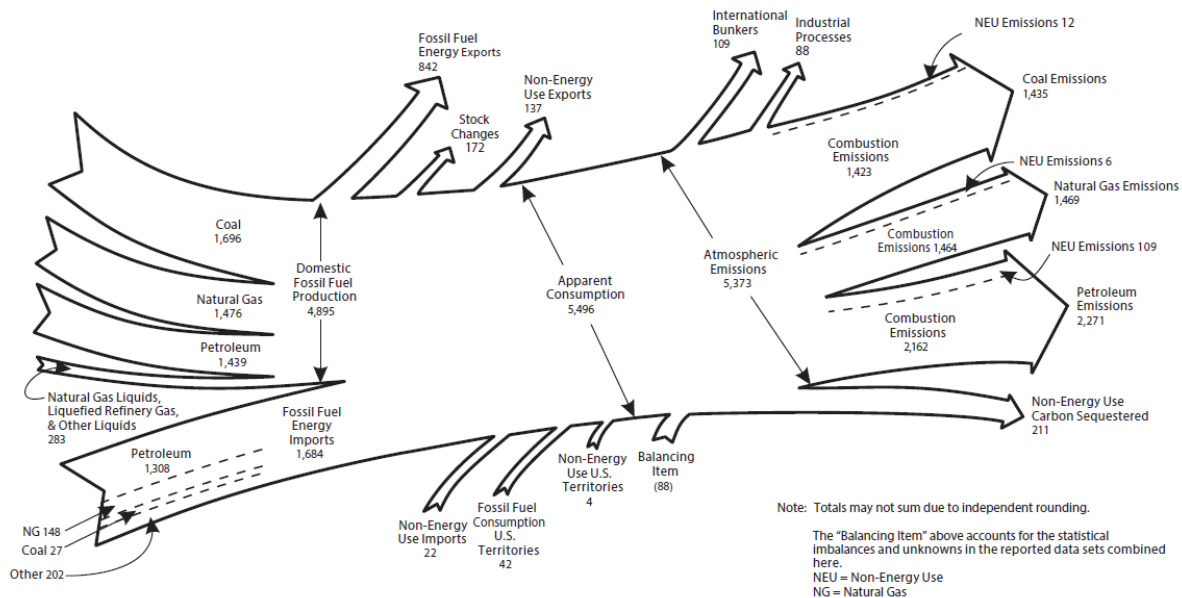

Figure 3-1: 2015 Energy Chapter Greenhouse Gas Sources (MMT CO₂ Eq.)

¹ Estimates are presented in units of million metric tons of carbon dioxide equivalent (MMT CO₂ Eq.), which weight each gas by its global warming potential, or GWP, value. See section on global warming potentials in the Executive Summary.

² Global CO₂ emissions from fossil fuel combustion were taken from International Energy Agency *CO₂ Emissions from Fossil Fuels Combustion – Highlights* <<https://www.iea.org/publications/freepublications/publication/co2-emissions-from-fuel-combustion-highlights-2016.html>> IEA (2016).

1 **Figure 3-2: 2015 U.S. Fossil Carbon Flows (MMT CO₂ Eq.)**

2
3 Energy-related activities other than fuel combustion, such as the production, transmission, storage, and distribution
4 of fossil fuels, also emit greenhouse gases. These emissions consist primarily of fugitive CH₄ from natural gas
5 systems, petroleum systems, and coal mining. Table 3-1 summarizes emissions from the Energy sector in units of
6 MMT CO₂ Eq., while unweighted gas emissions in kilotons (kt) are provided in Table 3-2. Overall, emissions due to
7 energy-related activities were 5,549.4 MMT CO₂ Eq. in 2015,³ an increase of 4.0 percent since 1990.

2 **Box 3-1: Methodological Approach for Estimating and Reporting U.S. Emissions and Sinks**

3 In following the United Nations Framework Convention on Climate Change (UNFCCC) requirement under Article
4 4.1 to develop and submit national greenhouse gas emission inventories, the emissions and sinks presented in this
5 report and this chapter, are organized by source and sink categories and calculated using internationally-accepted
6 methods provided by the Intergovernmental Panel on Climate Change (IPCC). Additionally, the calculated
7 emissions and sinks in a given year for the United States are presented in a common manner in line with the
8 UNFCCC reporting guidelines for the reporting of inventories under this international agreement. The use of
9 consistent methods to calculate emissions and sinks by all nations providing their inventories to the UNFCCC
10 ensures that these reports are comparable. In this regard, U.S. emissions and sinks reported in this Inventory are
11 comparable to emissions and sinks reported by other countries. Emissions and sinks provided in this Inventory do
12 not preclude alternative examinations, but rather, this Inventory presents emissions and sinks in a common format
13 consistent with how countries are to report Inventories under the UNFCCC. The report itself, and this chapter,
14 follows this standardized format, and provides an explanation of the IPCC methods used to calculate emissions and
15 sinks, and the manner in which those calculations are conducted.

Box 3-2: Energy Data from the Greenhouse Gas Reporting Program

On October 30, 2009, the U.S. Environmental Protection Agency (EPA) published a rule for the mandatory reporting of greenhouse gases from large greenhouse gas emissions sources in the United States. Implementation of 40 CFR Part 98 is referred to as the Greenhouse Gas Reporting Program (GHGRP). 40 CFR Part 98 applies to direct greenhouse gas emitters, fossil fuel suppliers, industrial gas suppliers, and facilities that inject CO₂ underground for sequestration or other reasons. Reporting is at the facility level, except for certain suppliers of fossil fuels and industrial greenhouse gases. 40 CFR part 98 requires reporting by 41 industrial categories. Data reporting by affected facilities included the reporting of emissions from fuel combustion at that affected facility. In general, the threshold for reporting is 25,000 metric tons or more of CO₂ Eq. per year.

EPA's GHGRP dataset and the data presented in this Inventory report are complementary and, as indicated in the respective Planned Improvements sections for source categories in this chapter, EPA is analyzing how to use facility-level GHGRP data to improve the national estimates presented in this Inventory (see, also, Box 3-4). Most methodologies used in EPA's GHGRP are consistent with IPCC, though for EPA's GHGRP, facilities collect detailed information specific to their operations according to detailed measurement standards, which may differ with the more aggregated data collected for the Inventory to estimate total, national U.S. emissions. It should be noted that the definitions and provisions for reporting fuel types in EPA's GHGRP may differ from those used in the Inventory in meeting the UNFCCC reporting guidelines. In line with the UNFCCC reporting guidelines, the Inventory report is a comprehensive accounting of all emissions from fuel types identified in the IPCC guidelines and provides a separate reporting of emissions from biomass. Further information on the reporting categorizations in EPA's GHGRP and specific data caveats associated with monitoring methods in EPA's GHGRP has been provided on the GHGRP website.

EPA presents the data collected by its GHGRP through a data publication tool that allows data to be viewed in several formats including maps, tables, charts and graphs for individual facilities or groups of facilities.

3.1 Fossil Fuel Combustion (IPCC Source Category 1A)

Emissions from the combustion of fossil fuels for energy include the gases CO₂, CH₄, and N₂O. Given that CO₂ is the primary gas emitted from fossil fuel combustion and represents the largest share of U.S. total emissions, CO₂ emissions from fossil fuel combustion are discussed at the beginning of this section. Following that is a discussion of emissions of all three gases from fossil fuel combustion presented by sectoral breakdowns. Methodologies for estimating CO₂ from fossil fuel combustion also differ from the estimation of CH₄ and N₂O emissions from stationary combustion and mobile combustion. Thus, three separate descriptions of methodologies, uncertainties, recalculations, and planned improvements are provided at the end of this section. Total CO₂, CH₄, and N₂O emissions from fossil fuel combustion are presented in Table 3-3 and Table 3-4.

Table 3-3: CO₂, CH₄, and N₂O Emissions from Fossil Fuel Combustion (MMT CO₂ Eq.)

Gas	1990	2005	2011	2012	2013	2014	2015
CO ₂	4,740.7	5,747.1	5,227.7	5,024.7	5,157.6	5,202.1	5,049.2
CH ₄	14.1	10.2	9.3	8.8	10.1	10.2	9.0
N ₂ O	53.1	56.0	44.2	41.8	41.5	40.0	38.5
Total	4,807.9	5,813.4	5,281.2	5,075.3	5,209.2	5,252.3	5,096.7

Note: Totals may not sum due to independent rounding

1 **Table 3-4: CO₂, CH₄, and N₂O Emissions from Fossil Fuel Combustion (kt)**

Gas	1990	2005	2011	2012	2013	2014	2015
CO ₂	4,740,671	5,747,142	5,227,690	5,024,685	5,157,583	5,202,139	5,049,159
CH ₄	565	408	374	352	405	406	360
N ₂ O	178	188	148	140	139	134	129

2 **CO₂ from Fossil Fuel Combustion**

3 Carbon dioxide is the primary gas emitted from fossil fuel combustion and represents the largest share of U.S. total
 4 greenhouse gas emissions. Carbon dioxide emissions from fossil fuel combustion are presented in Table 3-5. In
 5 2015, CO₂ emissions from fossil fuel combustion decreased by 2.9 percent relative to the previous year. The
 6 decrease in CO₂ emissions from fossil fuel combustion was a result of multiple factors, including: (1) substitution
 7 from coal to natural gas consumption in the electric power sector; (2) warmer winter conditions in the first quarter of
 8 2015 resulting in a decreased demand for heating fuel in the residential and commercial sectors; and (3) a slight
 9 decrease in electricity demand. In 2015, CO₂ emissions from fossil fuel combustion were 5,049.2 MMT CO₂ Eq., or
 10 6.5 percent above emissions in 1990 (see Table 3-5).⁴

11 **Table 3-5: CO₂ Emissions from Fossil Fuel Combustion by Fuel Type and Sector (MMT CO₂**

NE (Not Estimated)

NO (Not Occurring)

^aAlthough not technically a fossil fuel, geothermal energy-related CO₂ emissions are included for reporting purposes.

Note: Totals may not sum due to independent rounding.

⁴ An additional discussion of fossil fuel emission trends is presented in the Trends in U.S. Greenhouse Gas Emissions chapter.

1 Trends in CO₂ emissions from fossil fuel combustion are influenced by many long-term and short-term factors. On a
 2 year-to-year basis, the overall demand for fossil fuels in the United States and other countries generally fluctuates in
 3 response to changes in general economic conditions, energy prices, weather, and the availability of non-fossil
 4 alternatives. For example, in a year with increased consumption of goods and services, low fuel prices, severe
 5 summer and winter weather conditions, nuclear plant closures, and lower precipitation feeding hydroelectric dams,
 6 there would likely be proportionally greater fossil fuel consumption than a year with poor economic performance,
 7 high fuel prices, mild temperatures, and increased output from nuclear and hydroelectric plants.

8 Longer-term changes in energy consumption patterns, however, tend to be more a function of aggregate societal
 9 trends that affect the scale of consumption (e.g., population, number of cars, size of houses, and number of houses),
 10 the efficiency with which energy is used in equipment (e.g., cars, power plants, steel mills, and light bulbs), and
 11 social planning and consumer behavior (e.g., walking, bicycling, or telecommuting to work instead of driving).

12 Carbon dioxide emissions also depend on the source of energy and its carbon (C) intensity. The amount of C in fuels
 13 varies significantly by fuel type. For example, coal contains the highest amount of C per unit of useful energy.
 14 Petroleum has roughly 75 percent of the C per unit of energy as coal, and natural gas has only about 55 percent.⁵
 15 Table 3-6 shows annual changes in emissions during the last five years for coal, petroleum, and natural gas in
 16 selected sectors.

17 **Table 3-6: Annual Change in CO₂ Emissions and Total 2015 Emissions from Fossil Fuel**

^a Excludes emissions from International Bunker Fuels.

^b Includes fuels and sectors not shown in table.

Note: Totals may not sum due to independent rounding.

19 In the United States, 82 percent of the energy consumed in 2015 was produced through the combustion of fossil
 20 fuels such as coal, natural gas, and petroleum (see Figure 3-3 and Figure 3-4). The remaining portion was supplied
 21 by nuclear electric power (9 percent) and by a variety of renewable energy sources (10 percent), primarily
 22 hydroelectric power, wind energy and biofuels (EIA 2016a).⁶ Specifically, petroleum supplied the largest share of
 23 domestic energy demands, accounting for 37 percent of total U.S. energy consumption in 2015. Natural gas and coal
 24 followed in order of energy demand importance, accounting for approximately 29 percent and 16 percent of total
 25 U.S. energy consumption, respectively. Petroleum was consumed primarily in the transportation end-use sector and
 26 the vast majority of coal was used in electricity generation. Natural gas was broadly consumed in all end-use sectors
 27 except transportation (see Figure 3-5) (EIA 2016a).

⁵ Based on national aggregate carbon content of all coal, natural gas, and petroleum fuels combusted in the United States.

⁶ Renewable energy, as defined in EIA's energy statistics, includes the following energy sources: hydroelectric power, geothermal energy, biofuels, solar energy, and wind energy.

1 **Figure 3-3: 2015 U.S. Energy Consumption by Energy Source (Percent)**

2
3 **Figure 3-4: U.S. Energy Consumption (Quadrillion Btu)**

4
5

1 **Figure 3-5: 2015 CO₂ Emissions from Fossil Fuel Combustion by Sector and Fuel Type (MMT**
 2 **CO₂ Eq.)**

3
 4 Fossil fuels are generally combusted for the purpose of producing energy for useful heat and work. During the
 5 combustion process, the C stored in the fuels is oxidized and emitted as CO₂ and smaller amounts of other gases,
 6 including CH₄, CO, and NMVOCs.⁷ These other C containing non-CO₂ gases are emitted as a byproduct of
 7 incomplete fuel combustion, but are, for the most part, eventually oxidized to CO₂ in the atmosphere. Therefore, it is
 8 assumed all of the C in fossil fuels used to produce energy is eventually converted to atmospheric CO₂.

9
 10 **Box 3-3: Weather and Non-Fossil Energy Effects on CO₂ from Fossil Fuel Combustion Trends**

11 In 2015, weather conditions, and a warm first and fourth quarter of the year in particular, caused a significant
 12 decrease in energy demand for heating fuels and is reflected in the decreased residential emissions from 2014 to
 13 2015. The United States in 2015 also experienced a warmer winter overall compared to 2014, as heating degree days
 14 decreased (10.2 percent). Cooling degree days increased significantly by 14.6 percent and despite this increase in
 15 cooling degree days, residential electricity demand decreased slightly. Warmer winter conditions compared to 2014
 16 resulted in a decrease in the amount of energy required for heating, and heating degree days in the United States
 17 were 9.7 percent below normal (see Figure 3-6). Summer conditions were significantly warmer in 2015 compared to
 18 2014, with cooling degree days 22.5 percent above normal (see Figure 3-7) (EIA 2016a).⁸

⁷ See the sections entitled Stationary Combustion and Mobile Combustion in this chapter for information on non-CO₂ gas emissions from fossil fuel combustion.

⁸ Degree days are relative measurements of outdoor air temperature. Heating degree days are deviations of the mean daily temperature below 65 degrees Fahrenheit, while cooling degree days are deviations of the mean daily temperature above 65 degrees Fahrenheit. Heating degree days have a considerably greater effect on energy demand and related emissions than do cooling degree days. Excludes Alaska and Hawaii. Normals are based on data from 1971 through 2000. The variation in these normals during this time period was ±10 percent and ±14 percent for heating and cooling degree days, respectively (99 percent confidence interval).

1 **Figure 3-6: Annual Deviations from Normal Heating Degree Days for the United States**
 2 **(1950–2015, Index Normal = 100)**

3
 4 **Figure 3-7: Annual Deviations from Normal Cooling Degree Days for the United States**
 5 **(1950–2015, Index Normal = 100)**

6
 7 Although no new U.S. nuclear power plants were brought online in 2015, the utilization (i.e., capacity factors)⁹ of
 8 existing plants in 2015 remained high at 92 percent. Electricity output by hydroelectric power plants decreased in
 9 2015 by approximately 4 percent. In recent years, the wind power sector has been showing strong growth, such that,
 10 on the margin, it is becoming a relatively important electricity source. Electricity generated by nuclear plants in
 11 2015 provided more than 3 times as much of the energy generated in the United States from hydroelectric plants
 12 (EIA 2016a). Nuclear, hydroelectric, and wind power capacity factors since 1990 are shown in Figure 3-8.

⁹ The capacity factor equals generation divided by net summer capacity. Summer capacity is defined as "The maximum output that generating equipment can supply to system load, as demonstrated by a multi-hour test, at the time of summer peak demand (period of June 1 through September 30)." Data for both the generation and net summer capacity are from EIA (2016a).

 2 **States (1990–2015, Percent)**

5 Fossil Fuel Combustion Emissions by Sector

6 In addition to the CO₂ emitted from fossil fuel combustion, CH₄ and N₂O are emitted from stationary and mobile
 7 combustion as well. Table 3-7 provides an overview of the CO₂, CH₄, and N₂O emissions from fossil fuel
 8 combustion by sector.

9 **Table 3-7: CO₂, CH₄, and N₂O Emissions from Fossil Fuel Combustion by Sector (MMT CO₂**

U.S. Territories^a	28.0	50.1	41.7	43.7	43.7	41.4	41.4
Total	4,807.9	5,813.4	5,281.2	5,075.3	5,209.2	5,252.3	5,096.7

^a U.S. Territories are not apportioned by sector, and emissions are total greenhouse gas emissions from all fuel combustion sources.

Notes: Totals may not sum due to independent rounding. Emissions from fossil fuel combustion by electricity generation are allocated based on aggregate national electricity consumption by each end-use sector.

1 Other than CO₂, gases emitted from stationary combustion include the greenhouse gases CH₄ and N₂O and the
2 indirect greenhouse gases NO_x, CO, and NMVOCs.¹⁰ Methane and N₂O emissions from stationary combustion
3 sources depend upon fuel characteristics, size and vintage, along with combustion technology, pollution control
4 equipment, ambient environmental conditions, and operation and maintenance practices. Nitrous oxide emissions
5 from stationary combustion are closely related to air-fuel mixes and combustion temperatures, as well as the
6 characteristics of any pollution control equipment that is employed. Methane emissions from stationary combustion
7 are primarily a function of the CH₄ content of the fuel and combustion efficiency.

8 Mobile combustion produces greenhouse gases other than CO₂, including CH₄, N₂O, and indirect greenhouse gases
9 including NO_x, CO, and NMVOCs. As with stationary combustion, N₂O and NO_x emissions from mobile
10 combustion are closely related to fuel characteristics, air-fuel mixes, combustion temperatures, and the use of
11 pollution control equipment. N₂O from mobile sources, in particular, can be formed by the catalytic processes used
12 to control NO_x, CO, and hydrocarbon emissions. Carbon monoxide emissions from mobile combustion are
13 significantly affected by combustion efficiency and the presence of post-combustion emission controls. Carbon
14 monoxide emissions are highest when air-fuel mixtures have less oxygen than required for complete combustion.
15 These emissions occur especially in idle, low speed, and cold start conditions. Methane and NMVOC emissions
16 from motor vehicles are a function of the CH₄ content of the motor fuel, the amount of hydrocarbons passing
17 uncombusted through the engine, and any post-combustion control of hydrocarbon emissions (such as catalytic
18 converters).

19 An alternative method of presenting combustion emissions is to allocate emissions associated with electricity
20 generation to the sectors in which it is used. Four end-use sectors were defined: industrial, transportation, residential,
21 and commercial. In the table below, electricity generation emissions have been distributed to each end-use sector
22 based upon the sector's share of national electricity consumption, with the exception of CH₄ and N₂O from
23 transportation.¹¹ Emissions from U.S. Territories are also calculated separately due to a lack of end-use-specific
24 consumption data. This method assumes that emissions from combustion sources are distributed across the four end-
25 use sectors based on the ratio of electricity consumption in that sector. The results of this alternative method are
26 presented in Table 3-8.

27 **Table 3-8: CO₂, CH₄, and N₂O Emissions from Fossil Fuel Combustion by End-Use Sector**
28 **(MMT CO₂ Eq.)**

End-Use Sector	1990	2005	2011	2012	2013	2014	2015

CH ₄	1.1	1.2	1.2	1.1	1.2	1.2	1.2
N ₂ O	2.5	5.7	6.3	6.4	6.9	7.1	7.2
U.S. Territories^a	28.0	50.1	41.7	43.7	43.7	41.4	41.4
Total	4,807.9	5,813.4	5,281.2	5,075.3	5,209.2	5,252.3	5,096.7

^a U.S. Territories are not apportioned by sector, and emissions are total greenhouse gas emissions from all fuel combustion sources.

Notes: Totals may not sum due to independent rounding. Emissions from fossil fuel combustion by electricity generation are allocated based on aggregate national electricity consumption by each end-use sector.

1 Stationary Combustion

2 The direct combustion of fuels by stationary sources in the electricity generation, industrial, commercial, and
3 residential sectors represent the greatest share of U.S. greenhouse gas emissions. Table 3-9 presents CO₂ emissions
4 from fossil fuel combustion by stationary sources. The CO₂ emitted is closely linked to the type of fuel being
5 combusted in each sector (see Methodology section of CO₂ from Fossil Fuel Combustion). Other than CO₂, gases
6 emitted from stationary combustion include the greenhouse gases CH₄ and N₂O. Table 3-10 and Table 3-11 present
7 CH₄ and N₂O emissions from the combustion of fuels in stationary sources.¹² Methane and N₂O emissions from
8 stationary combustion sources depend upon fuel characteristics, combustion technology, pollution control
9 equipment, ambient environmental conditions, and operation and maintenance practices. Nitrous oxide emissions
10 from stationary combustion are closely related to air-fuel mixes and combustion temperatures, as well as the
11 characteristics of any pollution control equipment that is employed. Methane emissions from stationary combustion
12 are primarily a function of the CH₄ content of the fuel and combustion efficiency. The CH₄ and N₂O emission
13 estimation methodology was revised in 2010 to utilize the facility-specific technology and fuel use data reported to
14 EPA's Acid Rain Program (EPA 2016a) (see Methodology section for CH₄ and N₂O from Stationary Combustion).
15 Refer to Table 3-7 for the corresponding presentation of all direct emission sources of fuel combustion.

1 Electricity Generation

2 The process of generating electricity is the single largest source of CO₂ emissions in the United States, representing
3 35 percent of total CO₂ emissions from all CO₂ emissions sources across the United States. Methane and N₂O
4 accounted for a small portion of emissions from electricity generation, representing less than 0.1 percent and 1.0
5 percent, respectively. Electricity generation also accounted for the largest share of CO₂ emissions from fossil fuel
6 combustion, approximately 37.6 percent in 2015. Methane and N₂O from electricity generation represented 4.9 and
7 50.7 percent of total CH₄ and N₂O emissions from fossil fuel combustion in 2015, respectively.

8 While emissions from the electric power sector have increased by 4 percent since 1990, the carbon intensity of the
9 electric power sector, in terms of CO₂ Eq. per QBtu has significantly decreased by 16 percent during that same
10 timeframe. This decarbonization of the electric power sector is a result of several key drivers. Coal-fired electricity
11 generation (in kilowatt-hours [kWh]) decreased from almost 54 percent of generation in 1990 to 34 percent in 2015.
12 This generation corresponded with an increase in natural gas and renewable energy generation, largely from wind
13 and solar energy. Natural gas generation (in kWh) represented 11 percent of electric power generation in 1990, and
14 increased over the 26 year period to represent 32 percent of electric power generation in 2015. This decoupling of
15 electricity generation and the resulting emissions is shown below in Figure 3-9.

16 Decreases in natural gas costs and the associated increase in natural gas generation, particularly between 2005 and
17 2015, was the main driver of the decrease in electric power sector carbon intensity. During this time period, the cost
18 of natural gas (in \$/MMBtu) decreased by 51 percent while the cost of coal (in \$/MMBtu) increased by 91 percent
19 (EIA 2016a). Between 1990 and 2015, renewable energy generation (in kWh) from solar and wind energy have
20 increased from 0.1 percent in 1990 to 5 percent in 2015, which also helped drive the decreases in the carbon
21 intensity of the electricity supply in the United States. This decrease in carbon intensity occurred even as total
22 electricity retail sales increased 39 percent, from 2,713 billion kWh in 1990 to 3,759 billion kWh in 2015.

1 **Figure 3-9: Electricity Generation (Billion kWh) and Emissions (MMT CO₂ Eq.)**

2
3

4 Electricity was consumed primarily in the residential, commercial, and industrial end-use sectors for lighting,
5 heating, electric motors, appliances, electronics, and air conditioning (see Figure 3-10).

6 **Figure 3-10: Electricity Generation Retail Sales by End-Use Sector (Billion kWh)**

7
8
9
10
11

The electric power industry includes all power producers, consisting of both regulated utilities and non-utilities (e.g. independent power producers, qualifying co-generators, and other small power producers). For the underlying energy data used in this chapter, the Energy Information Administration (EIA) places electric power generation into three functional categories: the electric power sector, the commercial sector, and the industrial sector. The electric

1 power sector consists of electric utilities and independent power producers whose primary business is the production
2 of electricity, while the other sectors consist of those producers that indicate their primary business is something
3 other than the production of electricity.¹³

4 The industrial, residential, and commercial end-use sectors, as presented in Table 3-8, were reliant on electricity for
5 meeting energy needs. The residential and commercial end-use sectors were especially reliant on electricity
6 consumption for lighting, heating, air conditioning, and operating appliances. In 2015, electricity sales to the
7 residential end-use sector decreased by 0.5 percent and sales to the commercial end-use sector increased by 0.5
8 percent, respectively. The trend in the residential sector can largely be attributed to warmer, less energy-intensive
9 winter conditions while the trend in the commercial sector can largely be attributed to a growing economy compared
10 to 2014. Electricity sales to the industrial sector in 2015 decreased approximately 3.4 percent. Overall, in 2015, the
11 amount of electricity generated (in kWh) and the amount of electricity consumed (in kWh) decreased approximately
12 0.4 percent and 0.1 percent, respectively, relative to the previous year, while CO₂ emissions from the electric power
13 sector decreased by 6.7 percent. The decrease in CO₂ emissions was a result of a significant decrease in the
14 consumption of coal and increase in the consumption of natural gas for electricity generation by 13.9 percent and
15 18.7 percent, respectively, in 2015, and a decrease in the consumption of petroleum for electricity generation by 6.6
16 percent.

17 Industrial Sector

18 Industrial sector CO₂, CH₄, and N₂O, emissions accounted for 16, 16, and 6 percent of CO₂, CH₄, and N₂O,
19 emissions from fossil fuel combustion, respectively. Carbon dioxide, CH₄, and N₂O emissions resulted from the
20 direct consumption of fossil fuels for steam and process heat production.

21 The industrial sector, per the underlying energy consumption data from EIA, includes activities such as
22 manufacturing, construction, mining, and agriculture. The largest of these activities in terms of energy consumption
23 is manufacturing, of which six industries—Petroleum Refineries, Chemicals, Paper, Primary Metals, Food, and
24 Nonmetallic Mineral Products—represent the vast majority of the energy use (EIA 2016a and EIA 2009b).

25 In theory, emissions from the industrial sector should be highly correlated with economic growth and industrial
26 output, but heating of industrial buildings and agricultural energy consumption are also affected by weather
27 conditions.¹⁴ In addition, structural changes within the U.S. economy that lead to shifts in industrial output away
28 from energy-intensive manufacturing products to less energy-intensive products (e.g., from steel to computer
29 equipment) also have a significant effect on industrial emissions.

30 From 2014 to 2015, total industrial production and manufacturing output increased by 0.3 percent (FRB 2016). Over
31 this period, output increased across production indices for Food, Petroleum Refineries, Chemicals, and Nonmetallic
32 Mineral Products, and decreased slightly for Primary Metals and Paper (see Figure 3-11). Through EPA's
33 Greenhouse Gas Reporting Program (GHGRP), specific industrial sector trends can be discerned from the overall
34 total EIA industrial fuel consumption data used for these calculations.

35 For example, from 2013 to 2014 the underlying EIA data showed increased consumption of natural gas and a
36 decrease in petroleum fuels in the industrial sector. EPA's GHGRP data highlights that chemical manufacturing and
37 nonmetallic mineral products were contributors to these trends.^{15,16}

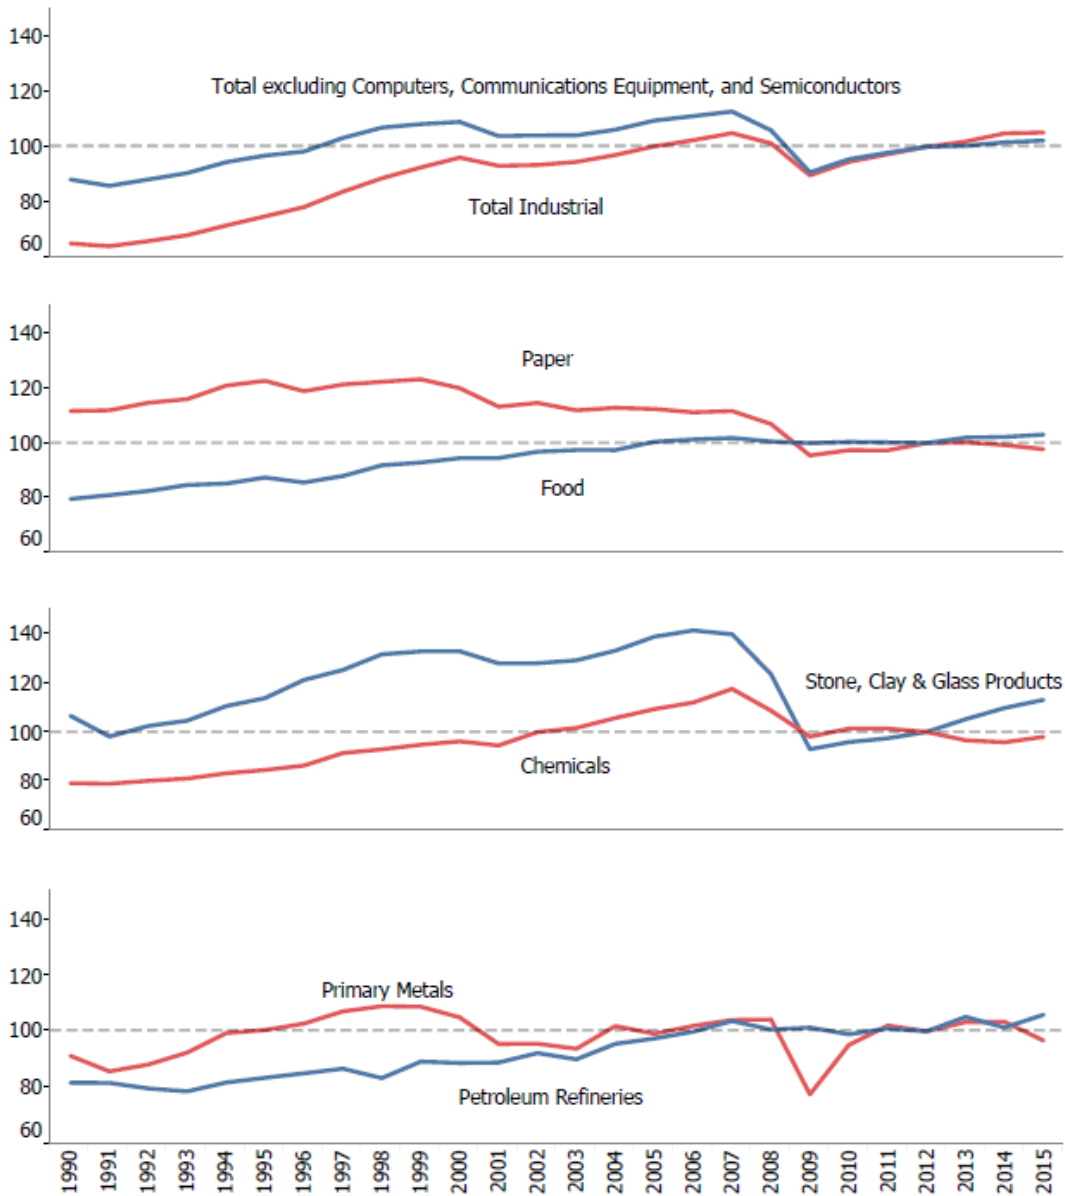

¹³ Utilities primarily generate power for the U.S. electric grid for sale to retail customers. Nonutilities produce electricity for their own use, to sell to large consumers, or to sell on the wholesale electricity market (e.g., to utilities for distribution and resale to customers).

¹⁴ Some commercial customers are large enough to obtain an industrial price for natural gas and/or electricity and are consequently grouped with the industrial end-use sector in U.S. energy statistics. These misclassifications of large commercial customers likely cause the industrial end-use sector to appear to be more sensitive to weather conditions.

¹⁵ Further details on industrial sector combustion emissions are provided by EPA's GHGRP. See <http://ghgdata.epa.gov/ghgp/main.do>.

¹⁶ U.S. EPA GHGRP 2015 data is not yet available. As a result, contributors to industrial trends have not yet been identified in the current Inventory and will be updated for the final Inventory report.

1 **Figure 3-11: Industrial Production Indices (Index 2007=100)**

2
 3 Despite the growth in industrial output (62 percent) and the overall U.S. economy (83 percent) from 1990 to 2015,
 4 CO₂ emissions from fossil fuel combustion in the industrial sector decreased by 1.6 percent over the same time
 5 series. A number of factors are believed to have caused this disparity between growth in industrial output and
 6 decrease in industrial emissions, including: (1) more rapid growth in output from less energy-intensive industries
 7 relative to traditional manufacturing industries, and (2) energy-intensive industries such as steel are employing new
 8 methods, such as electric arc furnaces, that are less carbon intensive than the older methods. In 2015, CO₂, CH₄, and
 9 N₂O emissions from fossil fuel combustion and electricity use within the industrial end-use sector totaled 1,378.2
 10 MMT CO₂ Eq., a 2.9 percent decrease from 2014 emissions.

11 **Residential and Commercial Sectors**

12 Residential and commercial sector CO₂ emissions accounted for 6 and 4 percent of CO₂ emissions from fossil fuel
 13 combustion, CH₄ emissions accounted for 43 and 12 percent of CH₄ emissions from fossil fuel combustion, and N₂O
 14 emissions accounted for 2 and 1 percent of N₂O emissions from fossil fuel combustion, respectively. Emissions

1 from these sectors were largely due to the direct consumption of natural gas and petroleum products, primarily for
2 heating and cooking needs. Coal consumption was a minor component of energy use in both of these end-use
3 sectors. In 2015, CO₂, CH₄, and N₂O emissions from fossil fuel combustion and electricity use within the residential
4 and commercial end-use sectors were 1,020.2 MMT CO₂ Eq. and 902.4 MMT CO₂ Eq., respectively. Total CO₂,
5 CH₄, and N₂O emissions from fossil fuel combustion and electricity use within the residential and commercial end-
6 use sectors decreased by 6.7 and 4.6 percent from 2014 to 2015, respectively.

7 Emissions from the residential and commercial sectors have generally been increasing since 1990, and are often
8 correlated with short-term fluctuations in energy consumption caused by weather conditions, rather than prevailing
9 economic conditions. In the long-term, both sectors are also affected by population growth, regional migration
10 trends, and changes in housing and building attributes (e.g., size and insulation).

11 In 2015, combustion emissions from natural gas consumption represent 79 and 78 percent of the direct fossil fuel
12 CO₂ emissions from the residential and commercial sectors, respectively. Natural gas combustion CO₂ emissions
13 from the residential and commercial sectors in 2015 decreased by 9.0 percent and 7.4 percent from 2014 levels,
14 respectively.

15 U.S. Territories

16 Emissions from U.S. Territories are based on the fuel consumption in American Samoa, Guam, Puerto Rico, U.S.
17 Virgin Islands, Wake Island, and other U.S. Pacific Islands. As described in the Methodology section of CO₂ from
18 Fossil Fuel Combustion, this data is collected separately from the sectoral-level data available for the general
19 calculations. As sectoral information is not available for U.S. Territories, CO₂, CH₄, and N₂O emissions are not
20 presented for U.S. Territories in the tables above, though the emissions will include some transportation and mobile
21 combustion sources.

22 Transportation Sector and Mobile Combustion

23 This discussion of transportation emissions follows the alternative method of presenting combustion emissions by
24 allocating emissions associated with electricity generation to the transportation end-use sector, as presented in Table
25 3-8. For direct emissions from transportation (i.e., not including emissions associated with the sector's electricity
26 consumption), please see Table 3-7.

27 *Transportation End-Use Sector*

28 The transportation end-use sector accounted for 1,754.5 MMT CO₂ Eq. in 2015, which represented 34 percent of
29 CO₂ emissions, 23 percent of CH₄ emissions, and 40 percent of N₂O emissions from fossil fuel combustion,
30 respectively.¹⁷ Fuel purchased in the United States for international aircraft and marine travel accounted for an
31 additional 111.8 MMT CO₂ Eq. in 2015; these emissions are recorded as international bunkers and are not included
32 in U.S. totals according to UNFCCC reporting protocols.

33 From 1990 to 2015, transportation emissions from fossil fuel combustion rose by 14 percent due, in large part, to
34 increased demand for travel. The number of vehicle miles traveled (VMT) by light-duty motor vehicles (passenger
35 cars and light-duty trucks) increased 42 percent from 1990 to 2015,¹⁸ as a result of a confluence of factors including
36 population growth, economic growth, urban sprawl, and periods of low fuel prices.

¹⁷ Note that these totals include CO₂, CH₄ and N₂O emissions from some sources in the U.S. Territories (ships and boats, recreational boats, non-transportation mobile sources) and CH₄ and N₂O emissions from transportation rail electricity.

¹⁸ VMT estimates are based on data from FHWA Highway Statistics Table VM-1 (FHWA 1996 through 2016). Table VM-1 data for 2015 has not been published yet, therefore 2015 mileage data is estimated using the 3.5 percent increase in FHWA Traffic Volume Trends from 2014 to 2015.

1 From 2014 to 2015, CO₂ emissions from the transportation end-use sector increased by 0.1 percent.^{19,20} The small
2 increase in emissions can be attributed to an increase in on-road distillate fuel oil and non-road fuel consumption,
3 particularly jet fuel, which is partly offset by a decrease in on-road motor gasoline consumption. It is important to
4 note, however, that the decrease in on-road motor gasoline consumption is likely due to a change in methods used to
5 estimate the share of gasoline used in on-road and non-road applications.²¹ Commercial aircraft emissions increased
6 slightly between 2014 and 2015, but have decreased 15 percent since 2007 (FAA 2017).²² Decreases in jet fuel
7 emissions (excluding bunkers) since 2007 are due in part to improved operational efficiency that results in more
8 direct flight routing, improvements in aircraft and engine technologies to reduce fuel burn and emissions, and the
9 accelerated retirement of older, less fuel efficient aircraft.

10 Almost all of the energy consumed for transportation was supplied by petroleum-based products, with more than
11 half being related to gasoline consumption in automobiles and other highway vehicles. Other fuel uses, especially
12 diesel fuel for freight trucks and jet fuel for aircraft, accounted for the remainder. The primary driver of
13 transportation-related emissions was CO₂ from fossil fuel combustion, which increased by 16 percent from 1990 to
14 2015. Annex 3.2 presents the total emissions from all transportation and mobile sources, including CO₂, N₂O, CH₄,
15 and HFCs.

16 *Transportation Fossil Fuel Combustion CO₂ Emissions*

17 Domestic transportation CO₂ emissions increased by 16 percent (240.1 MMT CO₂) between 1990 and 2015, an
18 annualized increase of 0.6 percent. Among domestic transportation sources, light-duty vehicles (including passenger
19 cars and light-duty trucks) represented 59 percent of CO₂ emissions from fossil fuel combustion, medium- and
20 heavy-duty trucks and buses 25 percent, commercial aircraft 7 percent, and other sources 9 percent. See
21 Table **3-12** for a detailed breakdown of transportation CO₂ emissions by mode and fuel type.

22 Almost all of the energy consumed by the transportation sector is petroleum-based, including motor gasoline, diesel
23 fuel, jet fuel, and residual oil. Carbon dioxide emissions from the combustion of ethanol and biodiesel for
24 transportation purposes, along with the emissions associated with the agricultural and industrial processes involved
25 in the production of biofuel, are captured in other Inventory sectors.²³ Ethanol consumption from the transportation
26 sector has increased from 0.7 billion gallons in 1990 to 13.4 billion gallons in 2015, while biodiesel consumption
27 has increased from 0.01 billion gallons in 2001 to 1.5 billion gallons in 2015. For further information, see the section
28 on biofuel consumption at the end of this chapter and Table A-95 in Annex 3.2.

29 Carbon dioxide emissions from passenger cars and light-duty trucks totaled 1,031.3 MMT CO₂ in 2015, an increase
30 of 9 percent (81.3 MMT CO₂) from 1990 due, in large part, to increased demand for travel as fleet-wide light-duty
31 vehicle fuel economy was relatively stable (average new vehicle fuel economy declined slowly from 1990 through
32 2004 and then increased more rapidly from 2005 through 2015). Carbon dioxide emissions from passenger cars and
33 light-duty trucks peaked at 1,180.5 MMT CO₂ in 2004, and since then have declined about 13 percent. The decline

¹⁹ Note that this value does not include lubricants.

²⁰ Note that EPA plans to integrate new data for the final 1990 to 2015 Inventory. As a result, the estimate of CO₂ emissions from the transportation end-use sector will likely decrease from 2014 to 2015 in the final Inventory. See Planned Improvements section for more detail.

²¹ In 2016, FHWA changed its methods for estimating the share of motor gasoline used in on-highway and off-highway applications. This resulted in an increase in the estimated off-highway motor gasoline consumption and subsequent decrease in the on-highway motor gasoline consumption for 2015. Among other updates, FHWA included lawn and garden equipment as well as off-road recreational equipment in its estimates of off-highway gasoline consumption for the first time. If this gasoline consumption had been attributed to the on-road sector in 2015, as it may have been in 2014 and previous years, the estimate of on-road gasoline would have increased in this Inventory from 2014 to 2015.

²² Commercial aircraft, as modeled in FAA's AEDT (FAA 2017), consists of passenger aircraft, cargo, and other chartered flights.

²³ Biofuel estimates are presented in the Energy chapter for informational purposes only, in line with IPCC methodological guidance and UNFCCC reporting obligations. Net carbon fluxes from changes in biogenic carbon reservoirs in croplands are accounted for in the estimates for Land Use, Land-Use Change, and Forestry (see Chapter 6). More information and additional analyses on biofuels are available at EPA's "Renewable Fuels: Regulations & Standards;" See <<http://www.epa.gov/otaq/fuels/renewablefuels/regulations.htm>>.

1 in new light-duty vehicle fuel economy between 1990 and 2004 (Figure 3-12) reflected the increasing market share
 2 of light-duty trucks, which grew from about 30 percent of new vehicle sales in 1990 to 48 percent in 2004. Starting
 3 in 2005, the rate of VMT growth slowed while average new vehicle fuel economy began to increase. Average new
 4 vehicle fuel economy has improved almost every year since 2005, and the truck share has decreased to about 43
 5 percent of new vehicles in model year 2015 (EPA 2016c).

6 Medium- and heavy-duty truck CO₂ emissions increased by 78 percent from 1990 to 2015. This increase was largely
 7 due to a substantial growth in medium- and heavy-duty truck VMT, which increased by 101 percent between 1990
 8 and 2015.²⁴ Carbon dioxide from the domestic operation of commercial aircraft increased by 8 percent (9.1 MMT
 9 CO₂) from 1990 to 2015.²⁵ Across all categories of aviation, excluding international bunkers, CO₂ emissions
 10 decreased by 15 percent (28.2 MMT CO₂) between 1990 and 2015.²⁶ This includes a 58 percent (20.3 MMT CO₂)
 11 decrease in CO₂ emissions from domestic military operations.

12 Transportation sources also produce CH₄ and N₂O; these emissions are included in Table 3-13 and Table 3-14 and in
 13 the CH₄ and N₂O from Mobile Combustion section. Annex 3.2 presents total emissions from all transportation and
 14 mobile sources, including CO₂, CH₄, N₂O, and HFCs.

15 **Figure 3-12: Sales-Weighted Fuel Economy of New Passenger Cars and Light-Duty Trucks,**
 16 **1990–2015 (miles/gallon)**

17
 18 Source: EPA (2016c)

²⁴ While FHWA data shows consistent growth in medium- and heavy-duty truck VMT over the 1990 to 2015 time period, part of the growth reflects a method change for estimating VMT starting in 2007. This change in methodology in FHWA’s VM-1 table resulted in large changes in VMT by vehicle class, thus leading to a shift in VMT and emissions among on-road vehicle classes in the 2007 to 2015 time period. During the time period prior to the method change (1990 to 2006), VMT for medium- and heavy-duty trucks increased by 51 percent.

²⁵ Commercial aircraft, as modeled in FAA’s AEDT, consists of passenger aircraft, cargo, and other chartered flights.

²⁶ Includes consumption of jet fuel and aviation gasoline. Does not include aircraft bunkers, which are not included in national emission totals, in line with IPCC methodological guidance and UNFCCC reporting obligations.

1 + Does not exceed 0.05 MMT CO₂ Eq.

2 ^a In 2011 FHWA changed its methods for estimating vehicle miles traveled (VMT) and related data. These methodological
3 changes included how vehicles are classified, moving from a system based on body-type to one that is based on wheelbase.
4 These changes were first incorporated for the 1990 through 2010 Inventory and apply to the 2007 through 2015 time period.
5 This resulted in large changes in VMT and fuel consumption data by vehicle class, thus leading to a shift in emissions among
6 on-road vehicle classes.

7 ^b Gasoline and diesel highway vehicle fuel consumption estimates are based on data from FHWA Highway Statistics Table MF-
8 21, MF-27, and VM-1 (FHWA 1996 through 2016). In 2016, FHWA changed its methods for estimating the share of motor
9 gasoline used in on-highway and off-highway applications. This resulted in an increase in the estimated off-highway motor
10 gasoline consumption and subsequent decrease in the on-highway motor gasoline consumption for 2015. Data from Table VM-1
11 is used to estimate the share of consumption between each on-road vehicle class. Since VM-1 data for 2015 has not been
12 published yet, fuel consumption shares from 2014 are used as a proxy for Public Review. These fuel consumption estimates are
13 combined with estimates of fuel shares by vehicle type from DOE's TEDB Annex Tables A.1 through A.6 (DOE 1993 through
14 2016). TEDB data for 2015 has not been published yet, therefore 2014 data is used as a proxy.

15 ^c Includes medium- and heavy-duty trucks over 8,500 lbs.

16 ^d In 2015, EPA incorporated the NONROAD2008 model into MOVES2014. The current Inventory uses the NONROAD
17 component of MOVES2014a for years 1999 through 2015.

18 ^e Note that large year over year fluctuations in emission estimates partially reflect nature of data collection for these sources.

19 ^f Official estimates exclude emissions from the combustion of both aviation and marine international bunker fuels; however,
20 estimates including international bunker fuel-related emissions are presented for informational purposes.

21 ^g Commercial aircraft, as modeled in FAA's AEDT, consists of passenger aircraft, cargo, and other chartered flights.

22 ^h Pipelines reflect CO₂ emissions from natural gas powered pipelines transporting natural gas.

23 ⁱ Ethanol estimates are presented for informational purposes only. See Section 3.10 of this chapter and the estimates in Land Use,
24 Land-Use Change, and Forestry (see Chapter 6), in line with IPCC methodological guidance and UNFCCC reporting
25 obligations, for more information on ethanol.

26 ^j Transportation sector natural gas and LPG consumption are based on data from EIA (2016). In prior Inventory years, data from
27 DOE TEDB was used to estimate each vehicle class's share of the total natural gas and LPG consumption. Since TEDB does
28 not include estimates for natural gas use by medium and heavy duty trucks or LPG use by passenger cars, EIA Alternative Fuel
29 Vehicle Data (Browning 2016) is now used to determine each vehicle class's share of the total natural gas and LPG
30 consumption. These changes were first incorporated in this year's Inventory and apply to the 1990 to 2015 time period.

31 Note: This table does not include emissions from non-transportation mobile sources, such as agricultural equipment and
32 construction/mining equipment; it also does not include emissions associated with electricity consumption by pipelines or
33 lubricants used in transportation. In addition, this table does not include CO₂ emissions from U.S. Territories, since these are
34 covered in a separate chapter of the Inventory. Totals may not sum due to independent rounding.
35

1 *Mobile Fossil Fuel Combustion CH₄ and N₂O Emissions*

2 Mobile combustion includes emissions of CH₄ and N₂O from all transportation sources identified in the U.S.
3 Inventory with the exception of pipelines and electric locomotives;²⁷ mobile sources also include non-transportation
4 sources such as construction/mining equipment, agricultural equipment, vehicles used off-road, and other sources
5 (e.g., snowmobiles, lawnmowers, etc.).²⁸ Annex 3.2 includes a summary of all emissions from both transportation
6 and mobile sources. Table 3-13 and Table 3-14 provide mobile fossil fuel CH₄ and N₂O emission estimates in MMT
7 CO₂ Eq.²⁹

8 Mobile combustion was responsible for a small portion of national CH₄ emissions (0.3 percent) but was the fourth
9 largest source of U.S. N₂O emissions (4.6 percent). From 1990 to 2015, mobile source CH₄ emissions declined by
10 64 percent, to 2.0 MMT CO₂ Eq. (82 kt CH₄), due largely to control technologies employed in on-road vehicles
11 since the mid-1990s to reduce CO, NO_x, NMVOC, and CH₄ emissions. Mobile source emissions of N₂O decreased
12 by 63 percent, to 15.4 MMT CO₂ Eq. (52 kt N₂O). Earlier generation control technologies initially resulted in higher
13 N₂O emissions, causing a 28 percent increase in N₂O emissions from mobile sources between 1990 and 1997.
14 Improvements in later-generation emission control technologies have reduced N₂O output, resulting in a 71 percent
15 decrease in mobile source N₂O emissions from 1997 to 2015 (Figure 3-14). Overall, CH₄ and N₂O emissions were
16 predominantly from gasoline-fueled passenger cars and light-duty trucks.

17 **Figure 3-14: Mobile Source CH₄ and N₂O Emissions (MMT CO₂ Eq.)**

18

²⁷ Emissions of CH₄ from natural gas systems are reported separately. More information on the methodology used to calculate these emissions are included in this chapter and Annex 3.4.

²⁸ See the methodology sub-sections of the CO₂ from Fossil Fuel Combustion and CH₄ and N₂O from Mobile Combustion sections of this chapter. Note that N₂O and CH₄ emissions are reported using different categories than CO₂. CO₂ emissions are reported by end-use sector (Transportation, Industrial, Commercial, Residential, U.S. Territories), and generally adhere to a top-down approach to estimating emissions. CO₂ emissions from non-transportation sources (e.g., lawn and garden equipment, farm equipment, construction equipment) are allocated to their respective end-use sector (i.e., construction equipment CO₂ emissions are included in the Industrial end-use sector instead of the Transportation end-use sector). CH₄ and N₂O emissions are reported using the “Mobile Combustion” category, which includes non-transportation mobile sources. CH₄ and N₂O emissions estimates are bottom-up estimates, based on total activity (fuel use, VMT) and emissions factors by source and technology type. These reporting schemes are in accordance with IPCC guidance. For informational purposes only, CO₂ emissions from non-transportation mobile sources are presented separately from their overall end-use sector in Annex 3.2.

²⁹ See Annex 3.2 for a complete time series of emission estimates for 1990 through 2015.

1 CO₂ from Fossil Fuel Combustion

2 Methodology

3 The methodology used by the United States for estimating CO₂ emissions from fossil fuel combustion is
4 conceptually similar to the approach recommended by the IPCC for countries that intend to develop detailed,
5 sectoral-based emission estimates in line with a Tier 2 method in the *2006 IPCC Guidelines for National
6 Greenhouse Gas Inventories* (IPCC 2006).³⁰ The use of the most recently published calculation methodologies by
7 the IPCC, as contained in the *2006 IPCC Guidelines*, is considered to improve the rigor and accuracy of this

³⁰ The IPCC Tier 3B methodology is used for estimating emissions from commercial aircraft.

1 Inventory and is fully in line with IPCC Good Practice Guidance. A detailed description of the U.S. methodology is
2 presented in Annex 2.1, and is characterized by the following steps:

- 3 1. *Determine total fuel consumption by fuel type and sector.* Total fossil fuel consumption for each year is
4 estimated by aggregating consumption data by end-use sector (e.g., commercial, industrial, etc.), primary
5 fuel type (e.g., coal, petroleum, gas), and secondary fuel category (e.g., motor gasoline, distillate fuel oil,
6 etc.). Fuel consumption data for the United States were obtained directly from the EIA of the U.S.
7 Department of Energy (DOE), primarily from the Monthly Energy Review and published supplemental
8 tables on petroleum product detail (EIA 2016a). The EIA does not include territories in its national energy
9 statistics, so fuel consumption data for territories were collected separately from EIA's International
10 Energy Statistics (EIA 2014) and Jacobs (2010).³¹

11 For consistency of reporting, the IPCC has recommended that countries report energy data using the
12 International Energy Agency (IEA) reporting convention and/or IEA data. Data in the IEA format are
13 presented "top down"—that is, energy consumption for fuel types and categories are estimated from energy
14 production data (accounting for imports, exports, stock changes, and losses). The resulting quantities are
15 referred to as "apparent consumption." The data collected in the United States by EIA on an annual basis
16 and used in this Inventory are predominantly from mid-stream or conversion energy consumers such as
17 refiners and electric power generators. These annual surveys are supplemented with end-use energy
18 consumption surveys, such as the Manufacturing Energy Consumption Survey, that are conducted on a
19 periodic basis (every four years). These consumption data sets help inform the annual surveys to arrive at
20 the national total and sectoral breakdowns for that total.³²

21 Also, note that U.S. fossil fuel energy statistics are generally presented using gross calorific values (GCV)
22 (i.e., higher heating values). Fuel consumption activity data presented here have not been adjusted to
23 correspond to international standards, which are to report energy statistics in terms of net calorific values
24 (NCV) (i.e., lower heating values).³³

- 25 2. *Subtract uses accounted for in the Industrial Processes and Product Use chapter.* Portions of the fuel
26 consumption data for seven fuel categories—coking coal, distillate fuel, industrial other coal, petroleum
27 coke, natural gas, residual fuel oil, and other oil—were reallocated to the Industrial Processes and Product
28 Use chapter, as they were consumed during non-energy related industrial activity. To make these
29 adjustments, additional data were collected from AISI (2004 through 2016), Coffeyville (2012), U.S.
30 Census Bureau (2001 through 2011), EIA (2016a, 2016b, 2016c), USAA (2008 through 2016), USGS
31 (1991 through 2015a), (USGS 2016a), USGS (2014 through 2016a), USGS (2014 through 2016b), USGS
32 (1995 through 2013), USGS (1995, 1998, 2000, 2001), USGS (2016b), USGS (20016c), USGS (2015a),
33 USGS (1991 through 2013), USGS (2016d), USGS (2015b), USGS (2014), USGS (1996 through 2013),
34 USGS (1991 through 2015b), USGS (2015 and 2016), USGS (1991 through 2015c).³⁴

- 35 3. *Adjust for conversion of fuels and exports of CO₂.* Fossil fuel consumption estimates are adjusted
36 downward to exclude fuels created from other fossil fuels and exports of CO₂.³⁵ Synthetic natural gas is
37 created from industrial coal, and is currently included in EIA statistics for both coal and natural gas.
38 Therefore, synthetic natural gas is subtracted from energy consumption statistics.³⁶ Since October 2000, the

³¹ Fuel consumption by U.S. Territories (i.e., American Samoa, Guam, Puerto Rico, U.S. Virgin Islands, Wake Island, and other U.S. Pacific Islands) is included in this report and contributed total emissions of 41.4 MMT CO₂ Eq. in 2015.

³² See IPCC Reference Approach for Estimating CO₂ Emissions from Fossil Fuel Combustion in Annex 4 for a comparison of U.S. estimates using top-down and bottom-up approaches.

³³ A crude convention to convert between gross and net calorific values is to multiply the heat content of solid and liquid fossil fuels by 0.95 and gaseous fuels by 0.9 to account for the water content of the fuels. Biomass-based fuels in U.S. energy statistics, however, are generally presented using net calorific values.

³⁴ See sections on Iron and Steel Production and Metallurgical Coke Production, Ammonia Production and Urea Consumption, Petrochemical Production, Titanium Dioxide Production, Ferroalloy Production, Aluminum Production, and Silicon Carbide Production and Consumption in the Industrial Processes and Product Use chapter.

³⁵ Energy statistics from EIA (2016a) are already adjusted downward to account for ethanol added to motor gasoline, biodiesel added to diesel fuel, and biogas in natural gas.

³⁶ These adjustments are explained in greater detail in Annex 2.1.

1 Dakota Gasification Plant has been exporting CO₂ to Canada by pipeline. Since this CO₂ is not emitted to
2 the atmosphere in the United States, energy used to produce this CO₂ is subtracted from energy
3 consumption statistics. To make these adjustments, additional data for ethanol and biodiesel were collected
4 from EIA (2016a), data for synthetic natural gas were collected from EIA (2016b), and data for CO₂
5 exports were collected from the Eastman Gasification Services Company (2011), Dakota Gasification
6 Company (2006), Fitzpatrick (2002), Erickson (2003), EIA (2008) and DOE (2012).

- 7 4. *Adjust Sectoral Allocation of Distillate Fuel Oil and Motor Gasoline.* EPA had conducted a separate
8 bottom-up analysis of transportation fuel consumption based on data from the Federal Highway
9 Administration that indicated that the amount of distillate and motor gasoline consumption allocated to the
10 transportation sector in the EIA statistics should be adjusted. Therefore, for these estimates, the
11 transportation sector's distillate fuel and motor gasoline consumption was adjusted to match the value
12 obtained from the bottom-up analysis. As the total distillate and motor gasoline consumption estimate from
13 EIA are considered to be accurate at the national level, the distillate and motor gasoline consumption totals
14 for the residential, commercial, and industrial sectors were adjusted proportionately. The data sources used
15 in the bottom-up analysis of transportation fuel consumption include AAR (2008 through 2016), Benson
16 (2002 through 2004), DOE (1993 through 2016), EIA (2007), EIA (1991 through 2016), EPA (2016d), and
17 FHWA (1996 through 2016).³⁷
- 18 5. *Adjust for fuels consumed for non-energy uses.* U.S. aggregate energy statistics include consumption of
19 fossil fuels for non-energy purposes. These are fossil fuels that are manufactured into plastics, asphalt,
20 lubricants, or other products. Depending on the end-use, this can result in storage of some or all of the C
21 contained in the fuel for a period of time. As the emission pathways of C used for non-energy purposes are
22 vastly different than fuel combustion (since the C in these fuels ends up in products instead of being
23 combusted), these emissions are estimated separately in Section 3.2 – Carbon Emitted and Stored in
24 Products from Non-Energy Uses of Fossil Fuels. Therefore, the amount of fuels used for non-energy
25 purposes was subtracted from total fuel consumption. Data on non-fuel consumption was provided by EIA
26 (2016a).
- 27 6. *Subtract consumption of international bunker fuels.* According to the UNFCCC reporting guidelines
28 emissions from international transport activities, or bunker fuels, should not be included in national totals.
29 U.S. energy consumption statistics include these bunker fuels (e.g., distillate fuel oil, residual fuel oil, and
30 jet fuel) as part of consumption by the transportation end-use sector, however, so emissions from
31 international transport activities were calculated separately following the same procedures used for
32 emissions from consumption of all fossil fuels (i.e., estimation of consumption, and determination of C
33 content).³⁸ The Office of the Under Secretary of Defense (Installations and Environment) and the Defense
34 Logistics Agency Energy (DLA Energy) of the U.S. Department of Defense (DoD) (DLA Energy 2016)
35 supplied data on military jet fuel and marine fuel use. Commercial jet fuel use was obtained from FAA
36 (2017); residual and distillate fuel use for civilian marine bunkers was obtained from DOC (1991 through
37 2016) for 1990 through 2001 and 2007 through 2014, and DHS (2008) for 2003 through 2006.
38 Consumption of these fuels was subtracted from the corresponding fuels in the transportation end-use
39 sector. Estimates of international bunker fuel emissions for the United States are discussed in detail in
40 Section 3.9 – International Bunker Fuels.
- 41 7. *Determine the total C content of fuels consumed.* Total C was estimated by multiplying the amount of fuel
42 consumed by the amount of C in each fuel. This total C estimate defines the maximum amount of C that
43 could potentially be released to the atmosphere if all of the C in each fuel was converted to CO₂. The C
44 content coefficients used by the United States were obtained from EIA's *Emissions of Greenhouse Gases in*
45 *the United States 2008* (EIA 2009a), and an EPA analysis of C content coefficients used in the GHGRP

³⁷ Bottom-up gasoline and diesel highway vehicle fuel consumption estimates are based on data from FHWA Highway Statistics Table MF-21, MF-27, and VM-1 (FHWA 1996 through 2016). In 2016, FHWA changed its methods for estimating the share of motor gasoline used in on-highway and off-highway applications. This resulted in an increase in the estimated off-highway motor gasoline consumption (including consumption in the commercial and industrial sectors of this Inventory) and subsequent decrease in the on-highway motor gasoline consumption for 2015. Note that EPA plans to integrate new 2014 data for the final 1990 to 2015 Inventory report, which is discussed in the Planned Improvements section below.

³⁸ See International Bunker Fuels section in this chapter for a more detailed discussion.

1 (EPA 2010). A discussion of the methodology used to develop the C content coefficients are presented in
2 Annexes 2.1 and 2.2.

- 3 8. *Estimate CO₂ Emissions.* Total CO₂ emissions are the product of the adjusted energy consumption (from
4 the previous methodology steps 1 through 6), the C content of the fuels consumed, and the fraction of C
5 that is oxidized. The fraction oxidized was assumed to be 100 percent for petroleum, coal, and natural gas
6 based on guidance in IPCC (2006) (see Annex 2.1).
- 7 9. *Allocate transportation emissions by vehicle type.* This report provides a more detailed accounting of
8 emissions from transportation because it is such a large consumer of fossil fuels in the United States. For
9 fuel types other than jet fuel, fuel consumption data by vehicle type and transportation mode were used to
10 allocate emissions by fuel type calculated for the transportation end-use sector. Heat contents and densities
11 were obtained from EIA (2016a) and USAF (1998).³⁹
- 12 • For on-road vehicles, annual estimates of combined motor gasoline and diesel fuel consumption by
13 vehicle category were obtained from FHWA (1996 through 2016); for each vehicle category, the
14 percent gasoline, diesel, and other (e.g., CNG, LPG) fuel consumption are estimated using data from
15 DOE (1993 through 2016).^{40,41}
 - 16 • For non-road vehicles, activity data were obtained from AAR (2008 through 2016), APTA (2007
17 through 2016), APTA (2006), BEA (2016), Benson (2002 through 2004), DOE (1993 through 2016),
18 DLA Energy (2016), DOC (1991 through 2016), DOT (1991 through 2016), EIA (2009a), EIA
19 (2016a), EIA (2013), EIA (1991 through 2016), EPA (2016d),⁴² and Gaffney (2007).
 - 20 • For jet fuel used by aircraft, CO₂ emissions from commercial aircraft were developed by the U.S.
21 Federal Aviation Administration (FAA) using a Tier 3B methodology, consistent IPCC (2006) (see
22 Annex 3.3). Carbon dioxide emissions from other aircraft were calculated directly based on reported
23 consumption of fuel as reported by EIA. Allocation to domestic military uses was made using DoD
24 data (see Annex 3.8). General aviation jet fuel consumption is calculated as the remainder of total jet
25 fuel use (as determined by EIA) nets all other jet fuel use as determined by FAA and DoD. For more
26 information, see Annex 3.2.

27
28 **Box 3-4: Uses of Greenhouse Gas Reporting Program Data and Improvements in Reporting Emissions from**
29 **Industrial Sector Fossil Fuel Combustion – TO BE UPDATED FOR FINAL INVENTORY REPORT**

30 As described in the calculation methodology, total fossil fuel consumption for each year is based on aggregated end-
31 use sector consumption published by the EIA. The availability of facility-level combustion emissions through EPA's

³⁹ For a more detailed description of the data sources used for the analysis of the transportation end use sector see the Mobile Combustion (excluding CO₂) and International Bunker Fuels sections of the Energy chapter, Annex 3.2, and Annex 3.8, respectively.

⁴⁰ Data from FHWA's Table VM-1 is used to estimate the share of fuel consumption between each on-road vehicle class. Since VM-1 data for 2015 has not been published yet, fuel consumption shares from 2014 are used as a proxy for the current Inventory. These fuel consumption estimates are combined with estimates of fuel shares by vehicle type from DOE's TEDB Annex Tables A.1 through A.6 (DOE 1993 through 2016). TEDB data for 2015 has not been published yet, therefore 2014 data is used as a proxy. In 2011, FHWA changed its methods for estimating data in the VM-1 table. These methodological changes included how vehicles are classified, moving from a system based on body-type to one that is based on wheelbase. These changes were first incorporated for the 1990 through 2010 Inventory and apply to the 2007 through 2015 time period. This resulted in large changes in VMT and fuel consumption data by vehicle class, thus leading to a shift in emissions among on-road vehicle classes.

⁴¹ Transportation sector natural gas and LPG consumption are based on data from EIA (2016). In prior Inventory years, data from DOE TEDB was used to estimate each vehicle class's share of the total natural gas and LPG consumption. Since TEDB does not include estimates for natural gas use by medium and heavy duty trucks or LPG use by passenger cars, EIA Alternative Fuel Vehicle Data (Browning 2016) is now used to determine each vehicle class's share of the total natural gas and LPG consumption. These changes were first incorporated in this year's Inventory and apply to the 1990 to 2015 time period.

⁴² In 2015, EPA incorporated the NONROAD2008 model into MOVES2014. The current Inventory uses the NONROAD component of MOVES2014a for years 1999 through 2015.

1 Greenhouse Gas Reporting Program (GHGRP) has provided an opportunity to better characterize the industrial
2 sector's energy consumption and emissions in the United States, through a disaggregation of EIA's industrial sector
3 fuel consumption data from select industries.

4 For EPA's GHGRP 2010 through 2015 reporting years, facility-level fossil fuel combustion emissions reported
5 through the GHGRP were categorized and distributed to specific industry types by utilizing facility-reported NAICS
6 codes (as published by the U.S. Census Bureau). As noted previously in this report, the definitions and provisions
7 for reporting fuel types in EPA's GHGRP include some differences from the Inventory's use of EIA national fuel
8 statistics to meet the UNFCCC reporting guidelines. The IPCC has provided guidance on aligning facility-level
9 reported fuels and fuel types published in national energy statistics, which guided this exercise.⁴³

10 This year's effort represents an attempt to align, reconcile, and coordinate the facility-level reporting of fossil fuel
11 combustion emissions under EPA's GHGRP with the national-level approach presented in this report. Consistent
12 with recommendations for reporting the Inventory to the UNFCCC, progress was made on certain fuel types for
13 specific industries and has been included in the Common Reporting Format (CRF) tables that are submitted to the
14 UNFCCC along with this report.⁴⁴ For the current exercise, the efforts in reconciling fuels focused on standard,
15 common fuel types (e.g., natural gas, distillate fuel oil, etc.) where the fuels in EIA's national statistics aligned well
16 with facility-level GHGRP data. For these reasons, the current information presented in the CRF tables should be
17 viewed as an initial attempt at this exercise. Additional efforts will be made for future Inventory reports to improve
18 the mapping of fuel types, and examine ways to reconcile and coordinate any differences between facility-level data
19 and national statistics. Additionally, this year's analysis expanded this effort through the full time series presented in
20 the CRF tables. Analyses were conducted linking GHGRP facility-level reporting with the information published by
21 EIA in its MECS data in order to disaggregate the full 1990 through 2015 time series in the CRF tables. It is
22 believed that the current analysis has led to improvements in the presentation of data in the Inventory, but further
23 work will be conducted, and future improvements will be realized in subsequent Inventory reports.

24 Additionally, to assist in the disaggregation of industrial fuel consumption, EIA will now synthesize energy
25 consumption data using the same procedure as is used for the last historical (benchmark) year of the Annual Energy
26 Outlook (AEO). This procedure reorganizes the most recent data from the Manufacturing Energy Consumption
27 Survey (MECS) (conducted every four years) into the nominal data submission year using the same energy-
28 economy integrated model used to produce the AEO projections, the National Energy Modeling System (NEMS).
29 EIA believes this "nowcasting" technique provides an appropriate estimate of energy consumption for the CRF.

30 To address gaps in the time series, EIA performs a NEMS model projection, using the MECS baseline sub-sector
31 energy consumption. The NEMS model accounts for changes in factors that influence industrial sector energy
32 consumption, and has access to data which may be more recent than MECS, such as industrial sub-sector macro
33 industrial output (i.e., shipments) and fuel prices. By evaluating the impact of these factors on industrial subsector
34 energy consumption, NEMS can anticipate changes to the energy shares occurring post-MECS and can provide a
35 way to appropriately disaggregate the energy-related emissions data into the CRF.

36 While the fuel consumption values for the various manufacturing sub-sectors are not directly surveyed for all years,
37 they represent EIA's best estimate of historical consumption values for non-MECS years. Moreover, as an integral
38 part of each AEO publication, this synthetic data series is likely to be maintained consistent with all available EIA
39 and non-EIA data sources even as the underlying data sources evolve for both manufacturing and non-
40 manufacturing industries alike.

41 Other sectors' fuel consumption (commercial, residential, transportation) will be benchmarked with the latest
42 aggregate values from the Monthly Energy Review.⁴⁵ EIA will work with EPA to back cast these values to 1990.

⁴³ See Section 4 "Use of Facility-Level Data in Good Practice National Greenhouse Gas Inventories" of the IPCC meeting report, and specifically the section on using facility-level data in conjunction with energy data, at <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

Box 3-5: Carbon Intensity of U.S. Energy Consumption

Fossil fuels are the dominant source of energy in the United States, and CO₂ is the dominant greenhouse gas emitted as a product from their combustion. Energy-related CO₂ emissions are impacted by not only lower levels of energy consumption but also by lowering the C intensity of the energy sources employed (e.g., fuel switching from coal to natural gas). The amount of C emitted from the combustion of fossil fuels is dependent upon the C content of the fuel and the fraction of that C that is oxidized. Fossil fuels vary in their average C content, ranging from about 53 MMT CO₂ Eq./QBTu for natural gas to upwards of 95 MMT CO₂ Eq./QBTu for coal and petroleum coke.⁴⁶ In general, the C content per unit of energy of fossil fuels is the highest for coal products, followed by petroleum, and then natural gas. The overall C intensity of the U.S. economy is thus dependent upon the quantity and combination of fuels and other energy sources employed to meet demand.

Table 3-15 provides a time series of the C intensity for each sector of the U.S. economy. The time series incorporates only the energy consumed from the direct combustion of fossil fuels in each sector. For the purposes of following reporting guidelines and maintaining the focus of this section, renewable energy and nuclear electricity and consumption are not included in the totals shown in Table 3-15 in order to focus attention on fossil fuel combustion as detailed in this chapter. For example, the C intensity for the residential sector does not include the energy from or emissions related to the consumption of electricity for lighting. Looking only at this direct consumption of fossil fuels, the residential sector exhibited the lowest C intensity, which is related to the large percentage of its energy derived from natural gas for heating. The C intensity of the commercial sector has predominantly declined since 1990 as commercial businesses shift away from petroleum to natural gas. The industrial sector was more dependent on petroleum and coal than either the residential or commercial sectors, and thus had higher C intensities over this period. The C intensity of the transportation sector was closely related to the C content of petroleum products (e.g., motor gasoline and jet fuel, both around 70 MMT CO₂ Eq./EJ), which were the primary sources of energy. Lastly, the electricity generation sector had the highest C intensity due to its heavy reliance on coal for generating electricity.

Table 3-15: Carbon Intensity from Direct Fossil Fuel Combustion by Sector (MMT CO₂ Eq./QBTu)

Sector	1990	2005	2011	2012	2013	2014	2015
Residential ^a	57.4	56.6	55.7	55.5	55.3	55.4	55.6
Commercial ^a	59.1	57.5	56.5	56.1	55.8	55.7	56.2
Industrial ^a	64.3	64.3	62.4	62.0	61.8	61.5	61.5
Transportation ^a	71.1	71.4	71.5	71.5	71.4	71.5	71.5
Electricity Generation ^b	87.3	85.8	82.9	79.9	81.3	81.2	78.1
U.S. Territories ^c	73.0	73.4	73.1	72.4	72.1	71.9	71.9
All Sectors^c	73.0	73.5	72.0	70.9	70.9	70.8	69.7

^a Does not include electricity or renewable energy consumption.

^b Does not include electricity produced using nuclear or renewable energy.

^c Does not include nuclear or renewable energy consumption.

Note: Excludes non-energy fuel use emissions and consumption.

For the time period of 1990 through about 2008, the C intensity of U.S. energy consumption was fairly constant, as the proportion of fossil fuels used by the individual sectors did not change significantly over that time. Starting in 2008 the C intensity has decreased, reflecting the shift from coal to natural gas in the electricity sector during that time period. Per capita energy consumption fluctuated little from 1990 to 2007, but in 2015 was approximately 10.2 percent below levels in 1990 (see Figure 3-15). To differentiate these estimates from those of Table 3-15, the C intensity trend shown in Figure 3-15 and described below includes nuclear and renewable energy EIA data to provide a comprehensive economy-wide picture of energy consumption. Due to a general shift from a manufacturing-based economy to a service-based economy, as well as overall increases in efficiency, energy consumption and energy-related CO₂ emissions per dollar of gross domestic product (GDP) have both declined since 1990 (BEA 2016).

⁴⁶ One exajoule (EJ) is equal to 10¹⁸ joules or 0.9478 QBTu.

Figure 3-15: U.S. Energy Consumption and Energy-Related CO₂ Emissions Per Capita and Per Dollar GDP

C intensity estimates were developed using nuclear and renewable energy data from EIA (2016a), EPA (2010), and fossil fuel consumption data as discussed above and presented in Annex 2.1.

Uncertainty and Time-Series Consistency – TO BE UPDATED FOR FINAL INVENTORY REPORT

For estimates of CO₂ from fossil fuel combustion, the amount of CO₂ emitted is directly related to the amount of fuel consumed, the fraction of the fuel that is oxidized, and the carbon content of the fuel. Therefore, a careful accounting of fossil fuel consumption by fuel type, average carbon contents of fossil fuels consumed, and production of fossil fuel-based products with long-term carbon storage should yield an accurate estimate of CO₂ emissions.

Nevertheless, there are uncertainties in the consumption data, carbon content of fuels and products, and carbon oxidation efficiencies. For example, given the same primary fuel type (e.g., coal, petroleum, or natural gas), the amount of carbon contained in the fuel per unit of useful energy can vary. For the United States, however, the impact of these uncertainties on overall CO₂ emission estimates is believed to be relatively small. See, for example, Marland and Pippin (1990).

Although statistics of total fossil fuel and other energy consumption are relatively accurate, the allocation of this consumption to individual end-use sectors (i.e., residential, commercial, industrial, and transportation) is less certain. For example, for some fuels the sectoral allocations are based on price rates (i.e., tariffs), but a commercial establishment may be able to negotiate an industrial rate or a small industrial establishment may end up paying an industrial rate, leading to a misallocation of emissions. Also, the deregulation of the natural gas industry and the more recent deregulation of the electric power industry have likely led to some minor problems in collecting accurate energy statistics as firms in these industries have undergone significant restructuring.

To calculate the total CO₂ emission estimate from energy-related fossil fuel combustion, the amount of fuel used in these non-energy production processes were subtracted from the total fossil fuel consumption. The amount of CO₂ emissions resulting from non-energy related fossil fuel use has been calculated separately and reported in the Carbon Emitted from Non-Energy Uses of Fossil Fuels section of this report (Section 3.2). These factors all contribute to the

1 uncertainty in the CO₂ estimates. Detailed discussions on the uncertainties associated with C emitted from Non-
 2 Energy Uses of Fossil Fuels can be found within that section of this chapter.

3 Various sources of uncertainty surround the estimation of emissions from international bunker fuels, which are
 4 subtracted from the U.S. totals (see the detailed discussions on these uncertainties provided in Section 3.9 –
 5 International Bunker Fuels). Another source of uncertainty is fuel consumption by U.S. Territories. The United
 6 States does not collect energy statistics for its territories at the same level of detail as for the fifty states and the
 7 District of Columbia. Therefore, estimating both emissions and bunker fuel consumption by these territories is
 8 difficult.

9 Uncertainties in the emission estimates presented above also result from the data used to allocate CO₂ emissions
 10 from the transportation end-use sector to individual vehicle types and transport modes. In many cases, bottom-up
 11 estimates of fuel consumption by vehicle type do not match aggregate fuel-type estimates from EIA. Further
 12 research is planned to improve the allocation into detailed transportation end-use sector emissions.

13 The uncertainty analysis was performed by primary fuel type for each end-use sector, using the IPCC-recommended
 14 Approach 2 uncertainty estimation methodology, Monte Carlo Stochastic Simulation technique, with @RISK
 15 software. For this uncertainty estimation, the inventory estimation model for CO₂ from fossil fuel combustion was
 16 integrated with the relevant variables from the inventory estimation model for International Bunker Fuels, to
 17 realistically characterize the interaction (or endogenous correlation) between the variables of these two models.
 18 About 120 input variables were modeled for CO₂ from energy-related Fossil Fuel Combustion (including about 10
 19 for non-energy fuel consumption and about 20 for International Bunker Fuels).

20 In developing the uncertainty estimation model, uniform distributions were assumed for all activity-related input
 21 variables and emission factors, based on the SAIC/EIA (2001) report.⁴⁷ Triangular distributions were assigned for
 22 the oxidization factors (or combustion efficiencies). The uncertainty ranges were assigned to the input variables
 23 based on the data reported in SAIC/EIA (2001) and on conversations with various agency personnel.⁴⁸

24 The uncertainty ranges for the activity-related input variables were typically asymmetric around their inventory
 25 estimates; the uncertainty ranges for the emissions factors were symmetric. Bias (or systematic uncertainties)
 26 associated with these variables accounted for much of the uncertainties associated with these variables (SAIC/EIA
 27 2001).⁴⁹ For purposes of this uncertainty analysis, each input variable was simulated 10,000 times through Monte
 28 Carlo sampling.

29 The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 3-16. Fossil fuel
 30 combustion CO₂ emissions in 2014 were estimated to be between 5,102.4 and 5,457.4 MMT CO₂ Eq. at a 95 percent
 31 confidence level. This indicates a range of 2 percent below to 5 percent above the 2014 emission estimate of 5,208.2
 32 MMT CO₂ Eq.

33 **Table 3-16: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Energy-
 34 Related Fossil Fuel Combustion by Fuel Type and Sector (MMT CO₂ Eq. and Percent)**

Fuel/Sector	2014 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
		(MMT CO ₂ Eq.)		(%)	
		Lower Bound	Upper Bound	Lower Bound	Upper Bound

⁴⁷ SAIC/EIA (2001) characterizes the underlying probability density function for the input variables as a combination of uniform and normal distributions (the former to represent the bias component and the latter to represent the random component). However, for purposes of the current uncertainty analysis, it was determined that uniform distribution was more appropriate to characterize the probability density function underlying each of these variables.

⁴⁸ In the SAIC/EIA (2001) report, the quantitative uncertainty estimates were developed for each of the three major fossil fuels used within each end-use sector; the variations within the sub-fuel types within each end-use sector were not modeled. However, for purposes of assigning uncertainty estimates to the sub-fuel type categories within each end-use sector in the current uncertainty analysis, SAIC/EIA (2001)-reported uncertainty estimates were extrapolated.

⁴⁹ Although, in general, random uncertainties are the main focus of statistical uncertainty analysis, when the uncertainty estimates are elicited from experts, their estimates include both random and systematic uncertainties. Hence, both these types of uncertainties are represented in this uncertainty analysis.

NE (Not Estimated)

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

^b The low and high estimates for total emissions were calculated separately through simulations and, hence, the low and high emission estimates for the sub-source categories do not sum to total emissions.

^c Geothermal emissions added for reporting purposes, but an uncertainty analysis was not performed for CO₂ emissions from geothermal production.

1 Methodological recalculations were applied to the entire time series to ensure time-series consistency from 1990
2 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
3 above.

4 QA/QC and Verification

5 A source-specific QA/QC plan for CO₂ from fossil fuel combustion was developed and implemented. This effort
6 included a Tier 1 analysis, as well as portions of a Tier 2 analysis. The Tier 2 procedures that were implemented
7 involved checks specifically focusing on the activity data and methodology used for estimating CO₂ emissions from
8 fossil fuel combustion in the United States. Emission totals for the different sectors and fuels were compared and
9 trends were investigated to determine whether any corrective actions were needed. Minor corrective actions were
10 taken.

11 Recalculations Discussion

12 The Energy Information Administration (EIA 2016a) updated energy consumption statistics across the time series
13 relative to the previous Inventory. EIA revised 2014 natural gas consumption in all end-use sectors, 2011 through
14 2014 Liquefied Petroleum Gas (LPG) consumption in all end-use sectors, 2014 coal and natural gas consumption in
15 the electric power sector, 2014 coal consumption in the commercial sector, and 2013 distillate fuel consumption in
16 the industrial and transportation sectors. In 2016, EIA revised 2014 heat contents for coal, coal coke, and natural
17 gas.

18 Overall, these changes resulted in an average annual decrease of 0.2 MMT CO₂ Eq. (less than 0.1 percent) in CO₂
19 emissions from fossil fuel combustion for the period 1990 through 2014, relative to the previous Inventory.

1 **Planned Improvements**

2 To reduce uncertainty of CO₂ from fossil fuel combustion estimates for U.S. Territories, efforts will continue to
3 work with EIA and other agencies to improve the quality of the U.S. Territories data. This improvement is not all-
4 inclusive, and is part of an ongoing analysis and efforts to continually improve the CO₂ from fossil fuel combustion
5 estimates. In addition, further expert elicitation may be conducted to better quantify the total uncertainty associated
6 with emissions from this source.

7 The availability of facility-level combustion emissions through EPA's GHGRP will continue to be examined to help
8 better characterize the industrial sector's energy consumption in the United States, and further classify total
9 industrial sector fossil fuel combustion emissions by business establishments according to industrial economic
10 activity type. Most methodologies used in EPA's GHGRP are consistent with IPCC, though for EPA's GHGRP,
11 facilities collect detailed information specific to their operations according to detailed measurement standards,
12 which may differ with the more aggregated data collected for the Inventory to estimate total, national U.S.
13 emissions. In addition, and unlike the reporting requirements for this chapter under the UNFCCC reporting
14 guidelines, some facility-level fuel combustion emissions reported under the GHGRP may also include industrial
15 process emissions.⁵⁰ In line with UNFCCC reporting guidelines, fuel combustion emissions are included in this
16 chapter, while process emissions are included in the Industrial Processes and Product Use chapter of this report. In
17 examining data from EPA's GHGRP that would be useful to improve the emission estimates for the CO₂ from fossil
18 fuel combustion category, particular attention will also be made to ensure time series consistency, as the facility-
19 level reporting data from EPA's GHGRP are not available for all inventory years as reported in this Inventory.
20 Additional analyses will be conducted to align reported facility-level fuel types and IPCC fuel types per the national
21 energy statistics. For example, efforts will be taken to incorporate updated industrial fuel consumption data from
22 EIA's Manufacturing Energy Consumption Survey (MECS), with updated data for 2014. Additional work will look
23 at CO₂ emissions from biomass to ensure they are separated in the facility-level reported data, and maintaining
24 consistency with national energy statistics provided by EIA. In implementing improvements and integration of data
25 from EPA's GHGRP, the latest guidance from the IPCC on the use of facility-level data in national inventories will
26 continue to be relied upon.⁵¹

27 An ongoing planned improvement is to develop improved estimates of domestic waterborne fuel consumption. The
28 Inventory estimates for residual and distillate fuel used by ships and boats is based in part on data on bunker fuel use
29 from the U.S. Department of Commerce. Domestic fuel consumption is estimated by subtracting fuel sold for
30 international use from the total sold in the United States. It may be possible to more accurately estimate domestic
31 fuel use and emissions by using detailed data on marine ship activity. The feasibility of using domestic marine
32 activity data to improve the estimates will continue to be investigated.

33 Lastly, an additional improvement for the final 1990 to 2015 Inventory is to update estimates of 2014 CO₂ emissions
34 from on-road gasoline consumption with FHWA's 2014 Table MF-21 published in July 2016. Estimates in this draft
35 Inventory are based on the 2014 Table MF-21 published in September 2015. Gasoline consumption for on-road
36 transportation in 2014 is estimated to be higher in the more recent FHWA data, which will result in a larger decrease
37 in on-road gasoline consumption from 2014 to 2015 than what is estimated in the current Inventory. As a result, the
38 estimate of CO₂ emissions from the overall transportation end-use sector will likely decrease from 2014 to 2015 in
39 the final Inventory. It is important to note, however, that the overall decrease in on-road motor gasoline consumption
40 from 2014 to 2015 is likely due to a change in FHWA methods used to estimate the share of gasoline used in on-
41 road and non-road applications in 2015. In absence of this method change, the estimate of on-road gasoline would
42 likely have increased in this Inventory from 2014 to 2015.

CH₄ and N₂O from Stationary Combustion

Methodology

Methane and N₂O emissions from stationary combustion were estimated by multiplying fossil fuel and wood consumption data by emission factors (by sector and fuel type for industrial, residential, commercial, and U.S. Territories; and by fuel and technology type for the electric power sector). Beginning with the current Inventory report, the electric power sector utilizes a Tier 2 methodology, whereas all other sectors utilize a Tier 1 methodology. The activity data and emission factors used are described in the following subsections.

Industrial, Residential, Commercial, and U.S. Territories

National coal, natural gas, fuel oil, and wood consumption data were grouped by sector: industrial, commercial, residential, and U.S. Territories. For the CH₄ and N₂O estimates, wood consumption data for the United States was obtained from EIA's Monthly Energy Review (EIA 2016a). Fuel consumption data for coal, natural gas, and fuel oil for the United States were also obtained from EIA's Monthly Energy Review and unpublished supplemental tables on petroleum product detail (EIA 2016a). Because the United States does not include territories in its national energy statistics, fuel consumption data for territories were provided separately by EIA's International Energy Statistics (EIA 2014) and Jacobs (2010).⁵² Fuel consumption for the industrial sector was adjusted to subtract out construction and agricultural use, which is reported under mobile sources.⁵³ Construction and agricultural fuel use was obtained from EPA (2016c) and FHWA (1996 through 2016). Estimates for wood biomass consumption for fuel combustion do not include wood wastes, liquors, municipal solid waste, tires, etc., that are reported as biomass by EIA. Tier 1 default emission factors for these three end-use sectors were provided by the *2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2006). U.S. Territories' emission factors were estimated using the U.S. emission factors for the primary sector in which each fuel was combusted.

Electric Power Sector

The electric power sector now uses a Tier 2 emission estimation methodology as fuel consumption for the electricity generation sector by control-technology type was obtained from EPA's Acid Rain Program Dataset (EPA 2016a). This combustion technology- and fuel-use data was available by facility from 1996 to 2015. The Tier 2 emission factors used were taken from IPCC (2006), which in turn are based on emission factors published by EPA.

Since there was a difference between the EPA (2016a) and EIA (2016a) total energy consumption estimates, the remaining energy consumption from EIA (2016a) was apportioned to each combustion technology type and fuel combination using a ratio of energy consumption by technology type from 1996 to 2015.

Energy consumption estimates were not available from 1990 to 1995 in the EPA (2016a) dataset, and as a result, consumption was calculated using total electric power consumption from EIA (2016a) and the ratio of combustion technology and fuel types from EPA (2016a). The consumption estimates from 1990 to 1995 were estimated by applying the 1996 consumption ratio by combustion technology type to the total EIA consumption for each year from 1990 to 1995. Emissions were estimated by multiplying fossil fuel and wood consumption by technology- and fuel-specific Tier 2 IPCC emission factors.

Lastly, there were significant differences between wood biomass consumption in the electric power sector between the EPA (2016a) and EIA (2016a) datasets. The higher wood biomass consumption from EIA (2016a) in the electric power sector was distributed to the residential, commercial, and industrial sectors according to their percent share of wood biomass energy consumption calculated from EIA (2016a).

⁵² U.S. Territories data also include combustion from mobile activities because data to allocate territories' energy use were unavailable. For this reason, CH₄ and N₂O emissions from combustion by U.S. Territories are only included in the stationary combustion totals.

⁵³ Though emissions from construction and farm use occur due to both stationary and mobile sources, detailed data was not available to determine the magnitude from each. Currently, these emissions are assumed to be predominantly from mobile sources.

1 More detailed information on the methodology for calculating emissions from stationary combustion, including
2 emission factors and activity data, is provided in Annex 3.1.

3 **Uncertainty and Time-Series Consistency – TO BE UPDATED FOR FINAL** 4 **INVENTORY REPORT**

5 Methane emission estimates from stationary sources exhibit high uncertainty, primarily due to difficulties in
6 calculating emissions from wood combustion (i.e., fireplaces and wood stoves). The estimates of CH₄ and N₂O
7 emissions presented are based on broad indicators of emissions (i.e., fuel use multiplied by an aggregate emission
8 factor for different sectors), rather than specific emission processes (i.e., by combustion technology and type of
9 emission control).

10 An uncertainty analysis was performed by primary fuel type for each end-use sector, using the IPCC-recommended
11 Approach 2 uncertainty estimation methodology, Monte Carlo Stochastic Simulation technique, with @RISK
12 software.

13 The uncertainty estimation model for this source category was developed by integrating the CH₄ and N₂O stationary
14 source inventory estimation models with the model for CO₂ from fossil fuel combustion to realistically characterize
15 the interaction (or endogenous correlation) between the variables of these three models. About 55 input variables
16 were simulated for the uncertainty analysis of this source category (about 20 from the CO₂ emissions from fossil
17 fuel combustion inventory estimation model and about 35 from the stationary source inventory models).

18 In developing the uncertainty estimation model, uniform distribution was assumed for all activity-related input
19 variables and N₂O emission factors, based on the SAIC/EIA (2001) report.⁵⁴ For these variables, the uncertainty
20 ranges were assigned to the input variables based on the data reported in SAIC/EIA (2001).⁵⁵ However, the CH₄
21 emission factors differ from those used by EIA. These factors and uncertainty ranges are based on IPCC default
22 uncertainty estimates (IPCC 2006).

23 The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 3-17. Stationary
24 combustion CH₄ emissions in 2014 (*including* biomass) were estimated to be between 4.8 and 20.6 MMT CO₂ Eq. at
25 a 95 percent confidence level. This indicates a range of 41 percent below to 155 percent above the 2014 emission
26 estimate of 8.1 MMT CO₂ Eq.⁵⁶ Stationary combustion N₂O emissions in 2014 (*including* biomass) were estimated
27 to be between 17.9 and 34.2 MMT CO₂ Eq. at a 95 percent confidence level. This indicates a range of 24 percent
28 below to 46 percent above the 2014 emissions estimate of 23.4 MMT CO₂ Eq.

⁵⁴ SAIC/EIA (2001) characterizes the underlying probability density function for the input variables as a combination of uniform and normal distributions (the former distribution to represent the bias component and the latter to represent the random component). However, for purposes of the current uncertainty analysis, it was determined that uniform distribution was more appropriate to characterize the probability density function underlying each of these variables.

⁵⁵ In the SAIC/EIA (2001) report, the quantitative uncertainty estimates were developed for each of the three major fossil fuels used within each end-use sector; the variations within the sub-fuel types within each end-use sector were not modeled. However, for purposes of assigning uncertainty estimates to the sub-fuel type categories within each end-use sector in the current uncertainty analysis, SAIC/EIA (2001)-reported uncertainty estimates were extrapolated.

⁵⁶ The low emission estimates reported in this section have been rounded down to the nearest integer values and the high emission estimates have been rounded up to the nearest integer values.

Table 3-17: Approach 2 Quantitative Uncertainty Estimates for CH₄ and N₂O Emissions from Energy-Related Stationary Combustion, Including Biomass (MMT CO₂ Eq. and Percent)

Source	Gas	2014 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a (MMT CO ₂ Eq.)			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Stationary Combustion	CH ₄	8.1	4.8	20.6	-41%	+155%
Stationary Combustion	N ₂ O	23.4	17.9	34.2	-24%	+46%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

The uncertainties associated with the emission estimates of CH₄ and N₂O are greater than those associated with estimates of CO₂ from fossil fuel combustion, which mainly rely on the carbon content of the fuel combusted. Uncertainties in both CH₄ and N₂O estimates are due to the fact that emissions are estimated based on emission factors representing only a limited subset of combustion conditions. For the indirect greenhouse gases, uncertainties are partly due to assumptions concerning combustion technology types, age of equipment, emission factors used, and activity data projections.

Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

QA/QC and Verification

A source-specific QA/QC plan for stationary combustion was developed and implemented. This effort included a Tier 1 analysis, as well as portions of a Tier 2 analysis. The Tier 2 procedures that were implemented involved checks specifically focusing on the activity data and emission factor sources and methodology used for estimating CH₄, N₂O, and the indirect greenhouse gases from stationary combustion in the United States. Emission totals for the different sectors and fuels were compared and trends were investigated.

Recalculations Discussion

Methane and N₂O emissions from stationary sources (excluding CO₂) across the entire time series were revised due to revised data from EIA (2016a) and EPA (2016a) relative to the previous Inventory. The historical data changes resulted in an average annual increase of less than 0.1 MMT CO₂ Eq. (less than 0.1 percent) in CH₄ emissions, and an average annual decrease of less than 0.1 MMT CO₂ Eq. (less than 0.1 percent) in N₂O emissions from stationary combustion for the period 1990 through 2014.

Planned Improvements

Several items are being evaluated to improve the CH₄ and N₂O emission estimates from stationary combustion and to reduce uncertainty for U.S. Territories. Efforts will be taken to work with EIA and other agencies to improve the quality of the U.S. Territories data. Because these data are not broken out by stationary and mobile uses, further research will be aimed at trying to allocate consumption appropriately. In addition, the uncertainty of biomass emissions will be further investigated since it was expected that the exclusion of biomass from the estimates would reduce the uncertainty; and in actuality the exclusion of biomass increases the uncertainty. These improvements are not all-inclusive, but are part of an ongoing analysis and efforts to continually improve these stationary combustion estimates from U.S. Territories.

Future improvements to the CH₄ and N₂O from Stationary Combustion category involve continued research into the availability of using CH₄ and N₂O from stationary combustion data from other sources, for example, data reported under EPA's GHGRP. In examining data from EPA's GHGRP that would be useful to improve the emission estimates for CH₄ and N₂O from Stationary Combustion category, particular attention will be made to ensure time series consistency, as the facility-level reporting data from EPA's GHGRP are not available for all Inventory years

1 as reported in this Inventory. In implementing improvements and integration of data from EPA’s GHGRP, the latest
2 guidance from the IPCC on the use of facility-level data in national inventories will be relied upon.⁵⁷

3 CH₄ and N₂O from Mobile Combustion

4 Methodology

5 Estimates of CH₄ and N₂O emissions from mobile combustion were calculated by multiplying emission factors by
6 measures of activity for each fuel and vehicle type (e.g., light-duty gasoline trucks). Activity data included vehicle
7 miles traveled (VMT) for on-road vehicles and fuel consumption for non-road mobile sources. The activity data and
8 emission factors used are described in the subsections that follow. A complete discussion of the methodology used to
9 estimate CH₄ and N₂O emissions from mobile combustion and the emission factors used in the calculations is provided
10 in Annex 3.2.

11 *On-Road Vehicles*

12 Estimates of CH₄ and N₂O emissions from gasoline and diesel on-road vehicles are based on VMT and emission
13 factors by vehicle type, fuel type, model year, and emission control technology. Emission estimates for alternative
14 fuel vehicles (AFVs) are based on VMT and emission factors by vehicle and fuel type.⁵⁸

15 Emission factors for gasoline and diesel on-road vehicles utilizing Tier 2 and Low Emission Vehicle (LEV)
16 technologies were developed by ICF (2006b); all other gasoline and diesel on-road vehicle emissions factors were
17 developed by ICF (2004). These factors were derived from EPA, California Air Resources Board (CARB) and
18 Environment Canada laboratory test results of different vehicle and control technology types. The EPA, CARB and
19 Environment Canada tests were designed following the Federal Test Procedure (FTP), which covers three separate
20 driving segments, since vehicles emit varying amounts of greenhouse gases depending on the driving segment.
21 These driving segments are: (1) a transient driving cycle that includes cold start and running emissions, (2) a cycle
22 that represents running emissions only, and (3) a transient driving cycle that includes hot start and running
23 emissions. For each test run, a bag was affixed to the tailpipe of the vehicle and the exhaust was collected; the
24 content of this bag was then analyzed to determine quantities of gases present. The emissions characteristics of
25 segment 2 were used to define running emissions, and subtracted from the total FTP emissions to determine start
26 emissions. These were then recombined based upon the ratio of start to running emissions for each vehicle class
27 from MOBILE6.2, an EPA emission factor model that predicts gram per mile emissions of CO₂, CO, HC, NO_x, and
28 PM from vehicles under various conditions, to approximate average driving characteristics.⁵⁹

29 Emission factors for AFVs were first developed by ICF (2006a) after examining Argonne National Laboratory’s
30 GREET 1.7–Transportation Fuel Cycle Model (ANL 2006) and Lipman and Delucchi (2002). These sources
31 describe AFV emission factors in terms of ratios to conventional vehicle emission factors. Ratios of AFV to
32 conventional vehicle emissions factors were then applied to estimated Tier 1 emissions factors from light-duty
33 gasoline vehicles to estimate light-duty AFVs. Emissions factors for heavy-duty AFVs were developed in relation to
34 gasoline heavy-duty vehicles. A complete discussion of the data source and methodology used to determine
35 emission factors from AFVs is provided in Annex 3.2.

36 Annual VMT data for 1990 through 2015 were obtained from the Federal Highway Administration’s (FHWA)
37 Highway Performance Monitoring System database as reported in Highway Statistics (FHWA 1996 through
38 2016).⁶⁰ VMT estimates were then allocated from FHWA’s vehicle categories to fuel-specific vehicle categories

⁵⁷ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

⁵⁸ Alternative fuel and advanced technology vehicles are those that can operate using a motor fuel other than gasoline or diesel. This includes electric or other bi-fuel or dual-fuel vehicles that may be partially powered by gasoline or diesel.

⁵⁹ Additional information regarding the model can be found online at <<http://www.epa.gov/OMS/m6.htm>>.

⁶⁰ The source of VMT is FHWA Highway Statistics Table VM-1. Since Table VM-1 data for 2015 has not been published yet, 2015 VMT is estimated using the 3.5 percent increase in FHWA Traffic Volume Trends data from 2014 to 2015. In 2011, FHWA changed its methods for estimating data in the VM-1 table. These methodological changes included how vehicles are

1 using the calculated shares of vehicle fuel use for each vehicle category by fuel type reported in DOE (1993 through
2 2016) and information on total motor vehicle fuel consumption by fuel type from FHWA (1996 through 2016).
3 VMT for AFVs were estimated based on Browning (2016). The age distributions of the U.S. vehicle fleet were
4 obtained from EPA (2016b, 2000), and the average annual age-specific vehicle mileage accumulation of U.S.
5 vehicles were obtained from EPA (2016b).

6 Control technology and standards data for on-road vehicles were obtained from EPA's Office of Transportation and
7 Air Quality (EPA 2007a, 2007b, 2000, 1998, and 1997) and Browning (2005). These technologies and standards are
8 defined in Annex 3.2, and were compiled from EPA (1994a, 1994b, 1998, 1999a) and IPCC (2006).

9 *Non-Road Vehicles*

10 To estimate emissions from non-road vehicles, fuel consumption data were employed as a measure of activity, and
11 multiplied by fuel-specific emission factors (in grams of N₂O and CH₄ per kilogram of fuel consumed).⁶¹ Activity
12 data were obtained from AAR (2008 through 2016), APTA (2007 through 2016), APTA (2006), BEA (1991 through
13 2015), Benson (2002 through 2004), DHS (2008), DLA Energy (2015), DOC (1991 through 2015), DOE (1993
14 through 2015), DOT (1991 through 2016), EIA (2002, 2007, 2016a), EIA (2007 through 2016), EIA (1991 through
15 2016), EPA (2016b), Esser (2003 through 2004), FAA (2017), FHWA (1996 through 2016),⁶² Gaffney (2007), and
16 Whorton (2006 through 2014). Emission factors for non-road modes were taken from IPCC (2006) and Browning
17 (2009).

18 **Uncertainty and Time-Series Consistency**

19 A quantitative uncertainty analysis was conducted for the mobile source sector using the IPCC-recommended
20 Approach 2 uncertainty estimation methodology, Monte Carlo Stochastic Simulation technique, using @RISK
21 software. The uncertainty analysis was performed on 2015 estimates of CH₄ and N₂O emissions, incorporating
22 probability distribution functions associated with the major input variables. For the purposes of this analysis, the
23 uncertainty was modeled for the following four major sets of input variables: (1) VMT data, by on-road vehicle and
24 fuel type and (2) emission factor data, by on-road vehicle, fuel, and control technology type, (3) fuel consumption,
25 data, by non-road vehicle and equipment type, and (4) emission factor data, by non-road vehicle and equipment
26 type.

27 Uncertainty analyses were not conducted for NO_x, CO, or NMVOC emissions. Emission factors for these gases have
28 been extensively researched since emissions of these gases from motor vehicles are regulated in the United States,
29 and the uncertainty in these emission estimates is believed to be relatively low. For more information, see Section
30 3.8 – Uncertainty Analysis of Emission Estimates. However, a much higher level of uncertainty is associated with
31 CH₄ and N₂O emission factors due to limited emission test data, and because, unlike CO₂ emissions, the emission
32 pathways of CH₄ and N₂O are highly complex.

33 Mobile combustion CH₄ emissions from all mobile sources in 2015 were estimated to be between 1.7 and 2.6 MMT
34 CO₂ Eq. at a 95 percent confidence level. This indicates a range of 18 percent below to 25 percent above the
35 corresponding 2015 emission estimate of 2.0 MMT CO₂ Eq. Also at a 95 percent confidence level, mobile
36 combustion N₂O emissions from mobile sources in 2015 were estimated to be between 13.4 and 18.1 MMT CO₂

classified, moving from a system based on body-type to one that is based on wheelbase. These changes were first incorporated
for the 1990 through 2010 Inventory and apply to the 2007 through 2015 time period. This resulted in large changes in VMT by
vehicle class, thus leading to a shift in emissions among on-road vehicle classes. For example, the category "Passenger Cars" has
been replaced by "Light-duty Vehicles-Short Wheelbase" and "Other 2 axle-4 Tire Vehicles" has been replaced by "Light-duty
Vehicles, Long Wheelbase." This change in vehicle classification has moved some smaller trucks and sport utility vehicles from
the light truck category to the passenger vehicle category in this Inventory. These changes are reflected in a large drop in light-
truck emissions between 2006 and 2007.

⁶¹ The consumption of international bunker fuels is not included in these activity data, but is estimated separately under the
International Bunker Fuels source category.

⁶² In 2016, FHWA changed its methods for estimating the share of motor gasoline used in on-highway and off-highway
applications. This resulted in an increase in the estimated off-highway motor gasoline consumption and subsequent decrease in
the on-highway motor gasoline consumption for 2015.

1 Eq., indicating a range of 13 percent below to 18 percent above the corresponding 2015 emission estimate of 15.4
 2 MMT CO₂ Eq.

3 **Table 3-18: Approach 2 Quantitative Uncertainty Estimates for CH₄ and N₂O Emissions from**
 4 **Mobile Sources (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate ^a (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Mobile Sources	CH ₄	2.0	1.7	2.6	-18%	+25%
Mobile Sources	N ₂ O	15.4	13.4	18.1	-13%	+18%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

5 This uncertainty analysis is a continuation of a multi-year process for developing quantitative uncertainty estimates
 6 for this source category using the IPCC Approach 2 uncertainty analysis. As a result, as new information becomes
 7 available, uncertainty characterization of input variables may be improved and revised. For additional information
 8 regarding uncertainty in emission estimates for CH₄ and N₂O please refer to the Uncertainty Annex.

9 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 10 through 2015 with two recent notable exceptions. First, an update to the method for estimating on-road VMT created
 11 an inconsistency in on-road CH₄ and N₂O for the time periods 1990 to 2006 and 2007 to 2015. Second, an update to
 12 the method for estimating share of motor gasoline used in on-highway and off-highway applications created an
 13 inconsistency in non-road CH₄ and N₂O for the time periods 1990 to 2014 and 2015. Details on the emission trends
 14 and methodological inconsistencies through time are described in more detail in the Methodology section, above.

15 QA/QC and Verification

16 A source-specific Quality Assurance/Quality Control plan for mobile combustion was developed and implemented.
 17 This plan is based on the IPCC-recommended QA/QC Plan. The specific plan used for mobile combustion was
 18 updated prior to collection and analysis of this current year of data. This effort included a Tier 1 analysis, as well as
 19 portions of a Tier 2 analysis. The Tier 2 procedures focused on the emission factor and activity data sources, as well
 20 as the methodology used for estimating emissions. These procedures included a qualitative assessment of the
 21 emissions estimates to determine whether they appear consistent with the most recent activity data and emission
 22 factors available. A comparison of historical emissions between the current Inventory and the previous Inventory
 23 was also conducted to ensure that the changes in estimates were consistent with the changes in activity data and
 24 emission factors.

25 Recalculations Discussion

26 Several updates were made to on-road CH₄ and N₂O emissions calculations this year resulting in a net increase to
 27 CH₄ and N₂O emissions from mobile combustion relative to the previous Inventory. First several light-duty trucks
 28 were re-characterized as heavy-duty vehicles based upon gross vehicle weight rating (GVWR) and confidential sales
 29 data. Second, which emission standards each vehicle type was assumed to have met were re-examined using
 30 confidential sales data. Also, in previous Inventories, non-plug-in hybrid electric vehicles (HEVs) were considered
 31 alternative fueled vehicles and therefore were not included in the engine technology breakouts. For this Inventory,
 32 HEVs are now classified as gasoline vehicles across the entire time series. PHEVs (plug-in hybrid electric vehicles)
 33 continue to be considered alternative fuel vehicles, as are electric vehicles. Estimates of alternative fuel vehicle
 34 mileage for the last ten years were revised to reflect updates made to Energy Information Administration (EIA) data
 35 on alternative fuel use and vehicle counts. Overall, these changes resulted in an average annual increase of 0.02
 36 MMT CO₂ Eq. (1 percent) in CH₄ emissions and an average annual increase of 0.5 MMT CO₂ Eq. (2 percent) in
 37 N₂O emissions from mobile combustion for the period 1990 through 2014, relative to the previous report.

1 **Planned Improvements**

2 While the data used for this report represent the most accurate information available, several areas have been
3 identified that could potentially be improved in the near term given available resources.

- 4 • Examine the 2016 FHWA off-highway gasoline methodology change—which impacted estimates of
5 commercial, industrial, agriculture, and construction CH₄ and N₂O mobile emissions in 2015—to determine
6 whether we should adjust other methods for estimating non-road equipment emissions.
- 7 • Continue to explore potential improvements to estimates of domestic waterborne fuel consumption for
8 future Inventories. The Inventory estimates for residual and distillate fuel used by ships and boats is based
9 in part on data on bunker fuel use from the U.S. Department of Commerce. Domestic fuel consumption is
10 estimated by subtracting fuel sold for international use from the total sold in the United States. It may be
11 possible to more accurately estimate domestic fuel use and emissions by using detailed data on marine ship
12 activity. The feasibility of using domestic marine activity data to improve the estimates continues to be
13 investigated. Additionally, the feasibility of including data from a broader range of domestic and
14 international sources for domestic bunker fuels, including data from studies such as the *Third IMO GHG*
15 *Study 2014*, continues to be explored.
- 16 • Continue to examine the use of EPA’s MOVES model in the development of the Inventory estimates,
17 including use for uncertainty analysis. Although the Inventory uses some of the underlying data from
18 MOVES, such as vehicle age distributions by model year, MOVES is not used directly in calculating
19 mobile source emissions. The use of MOVES is currently being evaluated to develop new emissions factors
20 for CH₄ and N₂O, which may be integrated into the final version of this Inventory or future inventories.
21 Other approaches for updating CH₄ and N₂O emissions factors, including use of the latest GREET model,
22 are also being considered.

23 **3.2 Carbon Emitted from Non-Energy Uses of** 24 **Fossil Fuels (IPCC Source Category 1A)**

25 In addition to being combusted for energy, fossil fuels are also consumed for non-energy uses (NEU) in the United
26 States. The fuels used for these purposes are diverse, including natural gas, liquefied petroleum gases (LPG), asphalt
27 (a viscous liquid mixture of heavy crude oil distillates), petroleum coke (manufactured from heavy oil), and coal
28 (metallurgical) coke (manufactured from coking coal). The non-energy applications of these fuels are equally
29 diverse, including feedstocks for the manufacture of plastics, rubber, synthetic fibers and other materials; reducing
30 agents for the production of various metals and inorganic products; and non-energy products such as lubricants,
31 waxes, and asphalt (IPCC 2006).

32 Carbon dioxide emissions arise from non-energy uses via several pathways. Emissions may occur during the
33 manufacture of a product, as is the case in producing plastics or rubber from fuel-derived feedstocks. Additionally,
34 emissions may occur during the product’s lifetime, such as during solvent use. Overall, throughout the time series
35 and across all uses, about 62 percent of the total C consumed for non-energy purposes was stored in products, and
36 not released to the atmosphere; the remaining 38 percent was emitted.

37 There are several areas in which non-energy uses of fossil fuels are closely related to other parts of this Inventory.
38 For example, some of the NEU products release CO₂ at the end of their commercial life when they are combusted
39 after disposal; these emissions are reported separately within the Energy chapter in the Incineration of Waste source
40 category. In addition, there is some overlap between fossil fuels consumed for non-energy uses and the fossil-
41 derived CO₂ emissions accounted for in the Industrial Processes and Product Use chapter, especially for fuels used
42 as reducing agents. To avoid double-counting, the “raw” non-energy fuel consumption data reported by EIA are
43 modified to account for these overlaps. There are also net exports of petrochemicals that are not completely
44 accounted for in the EIA data, and the Inventory calculations adjust for the effect of net exports on the mass of C in
45 non-energy applications.

1 As shown in Table 3-19, fossil fuel emissions in 2015 from the non-energy uses of fossil fuels were 127.0 MMT
 2 CO₂ Eq., which constituted approximately 2 percent of overall fossil fuel emissions. In 2015, the consumption of
 3 fuels for non-energy uses (after the adjustments described above) was 4,961.4 TBtu, an increase of 10.8 percent
 4 since 1990 (see Table 3-20). About 57.5 MMT (210.7 MMT CO₂ Eq.) of the C in these fuels was stored, while the
 5 remaining 34.6 MMT C (127.0 MMT CO₂ Eq.) was emitted.

6 **Table 3-19: CO₂ Emissions from Non-Energy Use Fossil Fuel Consumption (MMT CO₂ Eq. and**
 7 **Percent)**

Year	1990	2005	2011	2012	2013	2014	2015
Potential Emissions	312.1	377.4	316.6	311.9	327.1	322.0	324.1
C Stored	194.5	239.1	208.1	206.5	205.1	205.1	209.3
Emissions as a % of Potential	38%	37%	34%	34%	37%	36%	35%
Emissions	117.7	138.3	108.5	105.5	122.0	117.2	127.0

8 Methodology

9 The first step in estimating C stored in products was to determine the aggregate quantity of fossil fuels consumed for
 10 non-energy uses. The C content of these feedstock fuels is equivalent to potential emissions, or the product of
 11 consumption and the fuel-specific C content values. Both the non-energy fuel consumption and C content data were
 12 supplied by the EIA (2013, 2016) (see Annex 2.1). Consumption of natural gas, LPG, pentanes plus, naphthas, other
 13 oils, and special naphtha were adjusted to account for net exports of these products that are not reflected in the raw
 14 data from EIA. Consumption values for industrial coking coal, petroleum coke, other oils, and natural gas in Table
 15 3-20 and Table 3-21 have been adjusted to subtract non-energy uses that are included in the source categories of the
 16 Industrial Processes and Product Use chapter.^{63,64} Consumption values were also adjusted to subtract net exports of
 17 intermediary chemicals.

18 For the remaining non-energy uses, the quantity of C stored was estimated by multiplying the potential emissions by
 19 a storage factor.

- 20 • For several fuel types—petrochemical feedstocks (including natural gas for non-fertilizer uses, LPG,
 21 pentanes plus, naphthas, other oils, still gas, special naphtha, and industrial other coal), asphalt and road oil,
 22 lubricants, and waxes—U.S. data on C stocks and flows were used to develop C storage factors, calculated
 23 as the ratio of (a) the C stored by the fuel’s non-energy products to (b) the total C content of the fuel
 24 consumed. A lifecycle approach was used in the development of these factors in order to account for losses
 25 in the production process and during use. Because losses associated with municipal solid waste
 26 management are handled separately in the Energy sector under the Incineration of Waste source category,
 27 the storage factors do not account for losses at the disposal end of the life cycle.
- 28 • For industrial coking coal and distillate fuel oil, storage factors were taken from IPCC (2006), which in turn
 29 draws from Marland and Rotty (1984).
- 30 • For the remaining fuel types (petroleum coke, miscellaneous products, and other petroleum), IPCC does not
 31 provide guidance on storage factors, and assumptions were made based on the potential fate of C in the
 32 respective NEU products.

⁶³ These source categories include Iron and Steel Production, Lead Production, Zinc Production, Ammonia Manufacture, Carbon Black Manufacture (included in Petrochemical Production), Titanium Dioxide Production, Ferroalloy Production, Silicon Carbide Production, and Aluminum Production.

⁶⁴ Some degree of double counting may occur between these estimates of non-energy use of fuels and process emissions from petrochemical production presented in the Industrial Processes and Produce Use sector. Data integration is not feasible at this time as feedstock data from EIA used to estimate non-energy uses of fuels are aggregated by fuel type, rather than disaggregated by both fuel type and particular industries (e.g., petrochemical production) as currently collected through EPA’s GHGRP and used for the petrochemical production category.

1 **Table 3-20: Adjusted Consumption of Fossil Fuels for Non-Energy Uses (TBtu)**

Year	1990	2005	2011	2012	2013	2014	2015
Industry	4,215.8	5,110.7	4,470.1	4,377.3	4,621.1	4,597.3	4,759.6

NA - Not Applicable

^aTo avoid double counting, net exports have been deducted.

Note: Totals may not sum due to independent rounding.

1 Lastly, emissions were estimated by subtracting the C stored from the potential emissions (see Table 3-19). More
2 detail on the methodology for calculating storage and emissions from each of these sources is provided in Annex
3 2.3.

4 Where storage factors were calculated specifically for the United States, data were obtained on (1) products such as
5 asphalt, plastics, synthetic rubber, synthetic fibers, cleansers (soaps and detergents), pesticides, food additives,
6 antifreeze and deicers (glycols), and silicones; and (2) industrial releases including energy recovery, Toxics Release
7 Inventory (TRI) releases, hazardous waste incineration, and volatile organic compound, solvent, and non-
8 combustion CO emissions. Data were taken from a variety of industry sources, government reports, and expert
9 communications. Sources include EPA reports and databases such as compilations of air emission factors (EPA
10 2001), *National Emissions Inventory (NEI) Air Pollutant Emissions Trends Data* (EPA 2016a), *Toxics Release*
11 *Inventory, 1998* (EPA 2000b), *Biennial Reporting System* (EPA 2000a, 2009), *Resource Conservation and Recovery*
12 *Act Information System* (EPA 2013b, 2015b), pesticide sales and use estimates (EPA 1998, 1999, 2002, 2004, 2011),
13 and the Chemical Data Access Tool (EPA 2012); the EIA Manufacturer's Energy Consumption Survey (MECS)
14 (EIA 1994, 1997, 2001, 2005, 2010, 2013); the National Petrochemical & Refiners Association (NPROA 2002); the
15 U.S. Census Bureau (1999, 2004, 2009, 2014); Bank of Canada (2012, 2013, 2014, 2016); Financial Planning
16 Association (2006); INEGI (2006); the United States International Trade Commission (1990 through 2016);
17 Gosselin, Smith, and Hodge (1984); EPA's *Municipal Solid Waste (MSW) Facts and Figures* (EPA 2013a; 2014a,
18 2016b); the Rubber Manufacturers' Association (RMA 2009, 2011, 2014, 2016); the International Institute of
19 Synthetic Rubber Products (IISRP 2000, 2003); the Fiber Economics Bureau (FEB 2001, 2003, 2005, 2007, 2009,
20 2010, 2011, 2012, 2013); the EPA Chemical Data Access Tool (CDAT) (EPA 2014b); the American Chemistry
21 Council (ACC 2003 through 2011, 2013, 2014, 2015a); and the *Guide to the Business of Chemistry* (ACC 2012,
22 2015b, 2016). Specific data sources are listed in full detail in Annex 2.3.

23 **Uncertainty and Time-Series Consistency – TO BE UPDATED** 24 **FOR FINAL INVENTORY REPORT**

25 An uncertainty analysis was conducted to quantify the uncertainty surrounding the estimates of emissions and
26 storage factors from non-energy uses. This analysis, performed using @RISK software and the IPCC-recommended
27 Approach 2 methodology (Monte Carlo Stochastic Simulation technique), provides for the specification of
28 probability density functions for key variables within a computational structure that mirrors the calculation of the
29 inventory estimate. The results presented below provide the 95 percent confidence interval, the range of values
30 within which emissions are likely to fall, for this source category.

31 As noted above, the non-energy use analysis is based on U.S.-specific storage factors for (1) feedstock materials
32 (natural gas, LPG, pentanes plus, naphthas, other oils, still gas, special naphthas, and other industrial coal), (2)
33 asphalt, (3) lubricants, and (4) waxes. For the remaining fuel types (the "other" category in Table 3-20 and Table
34 3-21), the storage factors were taken directly from IPCC (2006), where available, and otherwise assumptions were
35 made based on the potential fate of carbon in the respective NEU products. To characterize uncertainty, five separate
36 analyses were conducted, corresponding to each of the five categories. In all cases, statistical analyses or expert
37 judgments of uncertainty were not available directly from the information sources for all the activity variables; thus,
38 uncertainty estimates were determined using assumptions based on source category knowledge.

39 The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 3-22 (emissions) and Table
40 3-23 (storage factors). Carbon emitted from non-energy uses of fossil fuels in 2014 was estimated to be between
41 86.2 and 162.9 MMT CO₂ Eq. at a 95 percent confidence level. This indicates a range of 25 percent below to 42

percent above the 2014 emission estimate of 114.3 MMT CO₂ Eq. The uncertainty in the emission estimates is a function of uncertainty in both the quantity of fuel used for non-energy purposes and the storage factor.

Table 3-22: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Non-Energy Uses of Fossil Fuels (MMT CO₂ Eq. and Percent)

Source	Gas	2014 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Feedstocks	CO ₂	75.1	49.6	125.3	-34%	67%
Asphalt	CO ₂	0.3	0.1	0.6	-57%	117%
Lubricants	CO ₂	18.9	15.5	21.9	-18%	16%
Waxes	CO ₂	0.5	0.3	0.7	-28%	63%
Other	CO ₂	19.6	14.1	21.7	-28%	11%
Total	CO₂	114.3	86.2	162.9	-25%	42%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Note: Totals may not sum due to independent rounding.

Table 3-23: Approach 2 Quantitative Uncertainty Estimates for Storage Factors of Non-Energy Uses of Fossil Fuels (Percent)

Source	Gas	2014 Storage Factor (%)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Feedstocks	CO ₂	65%	52%	72%	-20%	10%
Asphalt	CO ₂	99.6%	99.1%	99.8%	-0.5%	0.25%
Lubricants	CO ₂	9%	4%	17%	-57%	88%
Waxes	CO ₂	58%	49%	70%	-15%	22%
Other	CO ₂	4%	4%	24%	-3%	479%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval, as a percentage of the inventory value (also expressed in percent terms).

In Table 3-23, feedstocks and asphalt contribute least to overall storage factor uncertainty on a percentage basis. Although the feedstocks category—the largest use category in terms of total carbon flows—appears to have tight confidence limits, this is to some extent an artifact of the way the uncertainty analysis was structured. As discussed in Annex 2.3, the storage factor for feedstocks is based on an analysis of six fates that result in long-term storage (e.g., plastics production), and eleven that result in emissions (e.g., volatile organic compound emissions). Rather than modeling the total uncertainty around all of these fate processes, the current analysis addresses only the storage fates, and assumes that all C that is not stored is emitted. As the production statistics that drive the storage values are relatively well-characterized, this approach yields a result that is probably biased toward understating uncertainty.

As is the case with the other uncertainty analyses discussed throughout this document, the uncertainty results above address only those factors that can be readily quantified. More details on the uncertainty analysis are provided in Annex 2.3.

Methodological recalculations were applied to the entire time series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

1 QA/QC and Verification

2 A source-specific Quality Assurance/Quality Control plan for non-energy uses of fossil fuels was developed and
3 implemented. This effort included a Tier 1 analysis, as well as portions of a Tier 2 analysis for non-energy uses
4 involving petrochemical feedstocks and for imports and exports. The Tier 2 procedures that were implemented
5 involved checks specifically focusing on the activity data and methodology for estimating the fate of C (in terms of
6 storage and emissions) across the various end-uses of fossil C. Emission and storage totals for the different
7 subcategories were compared, and trends across the time series were analyzed to determine whether any corrective
8 actions were needed. Corrective actions were taken to rectify minor errors and to improve the transparency of the
9 calculations, facilitating future QA/QC.

10 For petrochemical import and export data, special attention was paid to NAICS numbers and titles to verify that
11 none had changed or been removed. Import and export totals were compared for 2014 as well as their trends across
12 the time series.

13 Petrochemical input data reported by EIA will continue to be investigated in an attempt to address an input/output
14 discrepancy in the NEU model. Since 2001, the C accounted for in the feedstocks C balance outputs (i.e., storage
15 plus emissions) exceeds C inputs. Prior to 2001, the C balance inputs exceed outputs. Starting in 2001 through 2009,
16 outputs exceeded inputs. In 2010 and 2011, inputs exceeded outputs, and in 2012, outputs slightly exceeded inputs.
17 A portion of this discrepancy has been reduced and two strategies have been developed to address the remaining
18 portion (see Planned Improvements, below).

19 Recalculations Discussion

20 A number of updates to historical production values were included in the most recent Monthly Energy Review; these
21 have been populated throughout this document.

22 Planned Improvements

23 There are several improvements planned for the future:

- 24 • Analyzing the fuel and feedstock data from EPA's GHGRP to better disaggregate CO₂ emissions in NEU
25 model and CO₂ process emissions from petrochemical production.
- 26 • More accurate accounting of C in petrochemical feedstocks. EPA has worked with EIA to determine the
27 cause of input/output discrepancies in the C mass balance contained within the NEU model. In the future,
28 two strategies to reduce or eliminate this discrepancy will continue to be pursued. First, accounting of C in
29 imports and exports will be improved. The import/export adjustment methodology will be examined to
30 ensure that net exports of intermediaries such as ethylene and propylene are fully accounted for. Second,
31 the use of top-down C input calculation in estimating emissions will be reconsidered. Alternative
32 approaches that rely more substantially on the bottom-up C output calculation will be considered instead.
- 33 • Response to potential changes in NEU input data. In 2013 EIA initiated implementation of new data
34 reporting definitions for Natural Gas Liquids (NGL) and Liquefied Petroleum Gases (LPG); the new
35 definitions may affect the characterization of the input data that EIA provides for the NEU model and may
36 therefore result in the need for changes to the NEU methodology. EIA also obtains and applies proprietary
37 data for LPG inputs that are not directly applied as NEU input data because the data are proprietary. The
38 potential use of the proprietary data (in an aggregated, non-proprietary form) as inputs to the NEU model
39 will be investigated with EIA.
- 40 • Improving the uncertainty analysis. Most of the input parameter distributions are based on professional
41 judgment rather than rigorous statistical characterizations of uncertainty.
- 42 • Better characterizing flows of fossil C. Additional fates may be researched, including the fossil C load in
43 organic chemical wastewaters, plasticizers, adhesives, films, paints, and coatings. There is also a need to
44 further clarify the treatment of fuel additives and backflows (especially methyl tert-butyl ether, MTBE).
- 45 • Reviewing the trends in fossil fuel consumption for non-energy uses. Annual consumption for several fuel

1 types is highly variable across the time series, including industrial coking coal and other petroleum
2 (miscellaneous products). A better understanding of these trends will be pursued to identify any
3 mischaracterized or misreported fuel consumption for non-energy uses. For example, “miscellaneous
4 products” category includes miscellaneous products that are not reported elsewhere in the EIA data set. The
5 EIA does not have firm data concerning the amounts of various products that are being reported in the
6 “miscellaneous products” category; however, EIA has indicated that recovered sulfur from petroleum and
7 natural gas processing, and potentially also C black feedstock could be reported in this category. Recovered
8 sulfur would not be reported in the NEU calculation or elsewhere in the Inventory.

- 9 • Updating the average C content of solvents was researched, since the entire time series depends on one
10 year’s worth of solvent composition data. The data on C emissions from solvents that were readily
11 available do not provide composition data for all categories of solvent emissions and also have conflicting
12 definitions for volatile organic compounds, the source of emissive C in solvents. Additional sources of
13 solvents data will be investigated in order to update the C content assumptions.
- 14 • Updating the average C content of cleansers (soaps and detergents) was researched; although production
15 and consumption data for cleansers are published every 5 years by the Census Bureau, the composition (C
16 content) of cleansers has not been recently updated. Recently available composition data sources may
17 facilitate updating the average C content for this category.
- 18 • Revising the methodology for consumption, production, and C content of plastics was researched; because
19 of recent changes to the type of data publicly available for plastics, the NEU model for plastics applies data
20 obtained from personal communications. Potential revisions to the plastics methodology to account for the
21 recent changes in published data will be investigated.
- 22 • Although U.S.-specific storage factors have been developed for feedstocks, asphalt, lubricants, and waxes,
23 default values from IPCC are still used for two of the non-energy fuel types (industrial coking coal,
24 distillate oil), and broad assumptions are being used for miscellaneous products and other petroleum. Over
25 the long term, there are plans to improve these storage factors by analyzing C fate similar to those
26 described in Annex 2.3 or deferring to more updated default storage factors from IPCC where available.
- 27 • Reviewing the storage of carbon black across various sectors in the Inventory; in particular, the carbon
28 black abraded and stored in tires.

29 **Box 3-6: Reporting of Lubricants, Waxes, and Asphalt and Road Oil Product Use in Energy Sector**

30 IPCC (2006) provides methodological guidance to estimate emissions from the first use of fossil fuels as a product
31 for primary purposes other than combustion for energy purposes (including lubricants, paraffin waxes, bitumen /
32 asphalt, and solvents) under the Industrial Processes and Product Use (IPPU) sector.⁶⁵ In this Inventory, C storage
33 and C emissions from product use of lubricants, waxes, and asphalt and road oil are reported under the Energy sector
34 in the Carbon Emitted from Non-Energy Uses of Fossil Fuels source category (IPCC Source Category 1A).⁶⁶

35 The emissions are reported in the Energy sector, as opposed to the IPPU sector, to reflect national circumstances in
36 its choice of methodology and to increase transparency of this source category’s unique country-specific data
37 sources and methodology. The country-specific methodology used for the Carbon Emitted from Non-Energy Uses of
38 Fossil Fuels source category is based on a carbon balance (i.e., C inputs-outputs) calculation of the aggregate
39 amount of fossil fuels used for non-energy uses, including inputs of lubricants, waxes, asphalt and road oil (see
40 Section 3.2, Table 3-21). For those inputs, U.S. country-specific data on C stocks and flows are used to develop
41 carbon storage factors, which are calculated as the ratio of the C stored by the fossil fuel non-energy products to the
42 total C content of the fuel consumed, taking into account losses in the production process and during product use.⁶⁷

⁶⁵ See Volume 3: Industrial Processes and Product Use, Chapter 5: Non-Energy Products from Fuels and Solvent Use of the
2006 IPCC Guidelines for National Greenhouse Gas Inventories (IPCC 2006).

⁶⁶ Non-methane volatile organic compound (NMVOC) emissions from solvent use are reported separately in the IPPU sector,
following Chapter 5 of the *2006 IPCC Guidelines*.

⁶⁷ Data and calculations for lubricants and waxes and asphalt and road oil are in Annex 2.3 – Methodology and Data for
Estimating CO₂ Emissions from Fossil Fuel Combustion.

1 The country-specific methodology to reflect national circumstances starts with the aggregate amount of fossil fuels
2 used for non-energy uses and applies a C balance calculation, breaking out the C emissions from non-energy use of
3 lubricants, waxes, and asphalt and road oil. Due to U.S. national circumstances, reporting these C emissions
4 separately under IPPU would involve making artificial adjustments to both the C inputs and C outputs of the non-
5 energy use C balance. These artificial adjustments would also result in the C emissions for lubricants, waxes, and
6 asphalt and road oil being reported under IPPU, while the C storage for lubricants, waxes, and asphalt and road oil
7 would be reported under Energy. To avoid presenting an incomplete C balance and a less transparent approach for
8 the Carbon Emitted from Non-Energy Uses of Fossil Fuels source category calculation, the entire calculation of C
9 storage and C emissions is therefore conducted in the Non-Energy Uses of Fossil Fuels category calculation
10 methodology, and both the C storage and C emissions for lubricants, waxes, and asphalt and road oil are reported
11 under the Energy sector.

12 3.3 Incineration of Waste (IPCC Source 13 Category 1A1a)

14 Incineration is used to manage about 7 to 19 percent of the solid wastes generated in the United States, depending on
15 the source of the estimate and the scope of materials included in the definition of solid waste (EPA 2000; Goldstein
16 and Madtes 2001; Kaufman et al. 2004; Simmons et al. 2006; van Haaren et al. 2010). In the context of this section,
17 waste includes all municipal solid waste (MSW) as well as scrap tires. In the United States, almost all incineration of
18 MSW occurs at waste-to-energy facilities or industrial facilities where useful energy is recovered, and thus
19 emissions from waste incineration are accounted for in the Energy chapter. Similarly, scrap tires are combusted for
20 energy recovery in industrial and utility boilers, pulp and paper mills, and cement kilns. Incineration of waste results
21 in conversion of the organic inputs to CO₂. According to IPCC guidelines, when the CO₂ emitted is of fossil origin,
22 it is counted as a net anthropogenic emission of CO₂ to the atmosphere. Thus, the emissions from waste incineration
23 are calculated by estimating the quantity of waste combusted and the fraction of the waste that is C derived from
24 fossil sources.

25 Most of the organic materials in municipal solid wastes are of biogenic origin (e.g., paper, yard trimmings), and
26 have their net C flows accounted for under the Land Use, Land-Use Change, and Forestry chapter. However, some
27 components—plastics, synthetic rubber, synthetic fibers, and carbon black in scrap tires—are of fossil origin.
28 Plastics in the U.S. waste stream are primarily in the form of containers, packaging, and durable goods. Rubber is
29 found in durable goods, such as carpets, and in non-durable goods, such as clothing and footwear. Fibers in
30 municipal solid wastes are predominantly from clothing and home furnishings. As noted above, scrap tires (which
31 contain synthetic rubber and carbon black) are also considered a “non-hazardous” waste and are included in the
32 waste incineration estimate, though waste disposal practices for tires differ from municipal solid waste. Estimates on
33 emissions from hazardous waste incineration can be found in Annex 2.3 and are accounted for as part of the C mass
34 balance for non-energy uses of fossil fuels.

35 Approximately 30.1 million metric tons of MSW were incinerated in the United States in 2014 (EPA 2016). Data for
36 the amount of MSW incinerated in 2015 were not available, so data for 2015 was assumed to be equal to data for
37 2014. CO₂ emissions from incineration of waste rose 34 percent since 1990, to an estimated 10.7 MMT CO₂ Eq.
38 (10,676 kt) in 2015, as the volume of scrap tires and other fossil C-containing materials in waste increased (see
39 Table 3-24 and Table 3-25). Waste incineration is also a source of CH₄ and N₂O emissions (De Soete 1993; IPCC
40 2006). Methane emissions from the incineration of waste were estimated to be less than 0.05 MMT CO₂ Eq. (less
41 than 0.5 kt CH₄) in 2015, and have decreased by 32 percent since 1990. Nitrous oxide emissions from the
42 incineration of waste were estimated to be 0.3 MMT CO₂ Eq. (1 kt N₂O) in 2015, and have decreased by 32 percent
43 since 1990.

44
45
46 **Table 3-24: CO₂, CH₄, and N₂O Emissions from the Incineration of Waste (MMT CO₂ Eq.)**

Gas/Waste Product	1990	2005	2011	2012	2013	2014	2015
CO₂	8.0	12.5	10.6	10.4	10.4	10.6	10.7

4

Methodology

5 Emissions of CO₂ from the incineration of waste include CO₂ generated by the incineration of plastics, synthetic
6 fibers, and synthetic rubber in MSW, as well as the incineration of synthetic rubber and carbon black in scrap tires.
7 The emission estimates are calculated for all four sources on a mass-basis based on the data available. These
8 emissions were estimated by multiplying the mass of each material incinerated by the C content of the material and
9 the fraction oxidized (98 percent). Plastics incinerated in municipal solid wastes were categorized into seven plastic
10 resin types, each material having a discrete C content. Similarly, synthetic rubber is categorized into three product
11 types, and synthetic fibers were categorized into four product types, each having a discrete C content. Scrap tires
12 contain several types of synthetic rubber, carbon black, and synthetic fibers. Each type of synthetic rubber has a
13 discrete C content, and carbon black is 100 percent C. Emissions of CO₂ were calculated based on the amount of
14 scrap tires used for fuel and the synthetic rubber and carbon black content of scrap tires. More detail on the
15 methodology for calculating emissions from each of these waste incineration sources is provided in Annex 3.7.

16 For each of the methods used to calculate CO₂ emissions from the incineration of waste, data on the quantity of
17 product combusted and the C content of the product are needed. For plastics, synthetic rubber, and synthetic fibers in
18 MSW, the amount of specific materials discarded as municipal solid waste (i.e., the quantity generated minus the
19 quantity recycled) was taken from *Municipal Solid Waste Generation, Recycling, and Disposal in the United States:
20 Facts and Figures* (EPA 2000 through 2003, 2005 through 2014), and *Advancing Sustainable Materials
21 Management: Facts and Figures: Assessing Trends in Material Generation, Recycling and Disposal in the United
22 States* (EPA 2015, 2016) and detailed unpublished backup data for some years not shown in the reports (Schneider
23 2007). For 2015, the amount of MSW incinerated was assumed to be equal to that in 2014, due to the lack of
24 available data. The proportion of total waste discarded that is incinerated was derived from Shin (2014). Data on
25 total waste incinerated was not available in detail for 2012 through 2015, so these values were assumed to equal to
26 the 2011 value (Shin 2014). For synthetic rubber and carbon black in scrap tires, information was obtained from
27 U.S. Scrap Tire Management Summary for 2005 through 2015 data (RMA 2016). Average C contents for the
28 “Other” plastics category and synthetic rubber in municipal solid wastes were calculated from 1998 and 2002
29 production statistics: C content for 1990 through 1998 is based on the 1998 value; C content for 1999 through 2001

1 is the average of 1998 and 2002 values; and C content for 2002 to date is based on the 2002 value. Carbon content
 2 for synthetic fibers was calculated from a weighted average of production statistics from 1990 to date. Information
 3 about scrap tire composition was taken from the Rubber Manufacturers' Association internet site (RMA 2012a). The
 4 mass of incinerated material is multiplied by its C content to calculate the total amount of carbon stored.

5 The assumption that 98 percent of organic C is oxidized (which applies to all waste incineration categories for CO₂
 6 emissions) was reported in EPA's life cycle analysis of greenhouse gas emissions and sinks from management of
 7 solid waste (EPA 2006). This percentage is multiplied by the carbon stored to estimate the amount of carbon
 8 emitted.

9 Incineration of waste, including MSW, also results in emissions of CH₄ and N₂O. These emissions were calculated
 10 as a function of the total estimated mass of waste incinerated and emission factors. As noted above, CH₄ and N₂O
 11 emissions are a function of total waste incinerated in each year; for 1990 through 2008, these data were derived from
 12 the information published in *BioCycle* (van Haaren et al. 2010). Data for 2009 and 2010 were interpolated between
 13 2008 and 2011 values. Data for 2011 were derived from Shin (2014). Data on total waste incinerated was not
 14 available in the *BioCycle* data set for 2012 through 2015, so these values were assumed to equal the 2011 *BioCycle*
 15 data set value.

16 Table 3-26 provides data on municipal solid waste discarded and percentage combusted for the total waste stream.
 17 The emission factors of N₂O and CH₄ emissions per quantity of municipal solid waste combusted are default
 18 emission factors for the default continuously-fed stoker unit MSW incineration technology type and were taken from
 19 IPCC (2006).

20 **Table 3-26: Municipal Solid Waste Generation (Metric Tons) and Percent Combusted**
 21 **(BioCycle dataset)**

Year	Waste Discarded	Waste Incinerated	Incinerated (% of Discards)
1990	235,733,657	30,632,057	13.0%
2005	259,559,787	25,973,520	10.0%
2011	273,116,704	20,756,870	7.6%
2012	273,116,704 ^a	20,756,870	7.6%
2013	273,116,704 ^a	20,756,870	7.6%
2014	273,116,704 ^a	20,756,870	7.6%
2015	273,116,704 ^a	20,756,870	7.6%

^a Assumed equal to 2011 value.

22 **Uncertainty and Time-Series Consistency – TO BE UPDATED** 23 **FOR FINAL INVENTORY REPORT**

24 An Approach 2 Monte Carlo analysis was performed to determine the level of uncertainty surrounding the estimates
 25 of CO₂ emissions and N₂O emissions from the incineration of waste (given the very low emissions for CH₄, no
 26 uncertainty estimate was derived). IPCC Approach 2 analysis allows the specification of probability density
 27 functions for key variables within a computational structure that mirrors the calculation of the Inventory estimate.
 28 Uncertainty estimates and distributions for waste generation variables (i.e., plastics, synthetic rubber, and textiles
 29 generation) were obtained through a conversation with one of the authors of the Municipal Solid Waste in the
 30 United States reports. Statistical analyses or expert judgments of uncertainty were not available directly from the
 31 information sources for the other variables; thus, uncertainty estimates for these variables were determined using
 32 assumptions based on source category knowledge and the known uncertainty estimates for the waste generation
 33 variables.

34 The uncertainties in the waste incineration emission estimates arise from both the assumptions applied to the data
 35 and from the quality of the data. Key factors include MSW incineration rate; fraction oxidized; missing data on

waste composition; average C content of waste components; assumptions on the synthetic/biogenic C ratio; and combustion conditions affecting N₂O emissions. The highest levels of uncertainty surround the variables that are based on assumptions (e.g., percent of clothing and footwear composed of synthetic rubber); the lowest levels of uncertainty surround variables that were determined by quantitative measurements (e.g., combustion efficiency, C content of C black).

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 3-27. Waste incineration CO₂ emissions in 2014 were estimated to be between 8.5 and 11.5 MMT CO₂ Eq. at a 95 percent confidence level. This indicates a range of 10 percent below to 14 percent above the 2014 emission estimate of 9.4 MMT CO₂ Eq. Also at a 95 percent confidence level, waste incineration N₂O emissions in 2014 were estimated to be between 0.1 and 0.8 MMT CO₂ Eq. This indicates a range of 53 percent below to 163 percent above the 2014 emission estimate of 0.3 MMT CO₂ Eq.

Table 3-27: Approach 2 Quantitative Uncertainty Estimates for CO₂ and N₂O from the Incineration of Waste (MMT CO₂ Eq. and Percent)

Source	Gas	2014 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Incineration of Waste	CO ₂	9.4	8.5	11.5	-10%	+14%
Incineration of Waste	N ₂ O	0.3	0.1	0.8	-53%	+163%

^a Range of emission estimates predicted by Monte Carlo Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

QA/QC and Verification

A source-specific Quality Assurance/Quality Control plan was implemented for incineration of waste. This effort included a Tier 1 analysis, as well as portions of a Tier 2 analysis. The Tier 2 procedures that were implemented involved checks specifically focusing on the activity data and specifically focused on the emission factor and activity data sources and methodology used for estimating emissions from incineration of waste. Trends across the time series were analyzed to determine whether any corrective actions were needed. Actions were taken to streamline the activity data throughout the calculations on incineration of waste.

Recalculations Discussion

For the current Inventory, emission estimates for 2014 have been updated based on *Advancing Sustainable Materials Management: 2014 Fact Sheet* (EPA 2016). The data used to calculate the percent incineration was not updated in the current Inventory. *Biocycle* has not released a new State of Garbage in America Report since 2010 (with 2008 data), which used to be a semi-annual publication which publishes the results of the nation-wide MSW survey. The results of the survey have been published in Shin (2014). This provided updated incineration data for 2011, so the generation and incineration data for 2012 through 2015 are assumed equivalent to the 2011 values. The data for 2009 and 2010 were based on interpolations between 2008 and 2011.

A transcription error in 2013 plastics production data from EPA's *Advancing Sustainable Materials Management: Facts and Figures 2013: Assessing Trends in Material Generation, Recycling and Disposal in the United States* (EPA 2015) was identified and corrected. The amount of HDPE discarded in 2013 was misreported and the value has been updated. This update results in updated emission estimate for the CO₂ from Plastics for 2013.

Previously, the carbon content for synthetic fiber was assumed to be the weighted average of carbon contents of four fiber types (polyester, nylon, olefin, and acrylic) based on 1999 fiber production data. This methodology has been updated. A weighted average for the carbon content of synthetic fibers based on production data from 1990 through 2015 was developed for each year based on the amount of fiber produced. For each year, the weighted average

1 carbon content was used to develop the amount of carbon emitted. This methodology update affects the synthetic
2 fiber CO₂ estimates.

3 **Planned Improvements**

4 The availability of facility-level waste incineration data through EPA’s Greenhouse Gas Reporting Program
5 (GHGRP) will be examined to help better characterize waste incineration operations in the United States. This
6 characterization could include future improvements as to the operations involved in waste incineration for energy,
7 whether in the power generation sector or the industrial sector. Additional examinations will be necessary as, unlike
8 the reporting requirements for this chapter under the UNFCCC reporting guidelines,⁶⁸ some facility-level waste
9 incineration emissions reported under EPA’s GHGRP may also include industrial process emissions. In line with
10 UNFCCC reporting guidelines, emissions for waste incineration with energy recovery are included in this chapter,
11 while process emissions are included in the Industrial Processes and Product Use chapter of this report. In
12 examining data from EPA’s GHGRP that would be useful to improve the emission estimates for the waste
13 incineration category, particular attention will also be made to ensure time series consistency, as the facility-level
14 reporting data from EPA’s GHGRP are not available for all inventory years as reported in this Inventory.
15 Additionally, analyses will focus on ensuring CO₂ emissions from the biomass component of waste are separated in
16 the facility-level reported data, and on maintaining consistency with national waste generation and fate statistics
17 currently used to estimate total, national U.S. greenhouse gas emissions. In implementing improvements and
18 integration of data from EPA’s GHGRP, the latest guidance from the IPCC on the use of facility-level data in
19 national inventories will be relied upon.⁶⁹ GHGRP data is available for MSW combustors, which contains
20 information on the CO₂, CH₄, and N₂O emissions from MSW combustion, plus the fraction of the emissions that are
21 biogenic. To calculate biogenic versus total CO₂ emissions, a default biogenic fraction of 0.6 is used. The biogenic
22 fraction will be calculated using the current input data and assumptions to verify the current MSW emission
23 estimates.

24 If GHGRP data would not provide a more accurate estimate of the amount of solid waste combusted, new data
25 sources for the total MSW generated will be explored given that the data previously published semi-annually in
26 Biocycle (van Haaren et al. 2010) has ceased to be published, according to the authors. Equivalent data was derived
27 from Shin (2014) for 2011. A new methodology would be developed considering the available data within the
28 annual update of EPA’s *Advancing Sustainable Materials Management: Facts and Figures 2014: Assessing Trends
29 in Material Generation, Recycling and Disposal in the United States* (EPA 2016) and a report from the
30 Environmental Research & Education Foundation (2016), *MSW Management in the U.S.: 2010 & 2013*, that has
31 data for 2010 and 2013. In developing the new methodology, appropriate assumptions would need to be made to
32 ensure that the MSW figures include the same boundaries. Consideration would also be made to be consistent with
33 calculations in other waste categories including landfilling and composting.

34 Additional improvements will be conducted to improve the transparency in the current reporting of waste
35 incineration. Currently, hazardous industrial waste incineration is included within the overall calculations for the
36 Carbon Emitted from Non-Energy Uses of Fossil Fuels source category. Waste incineration activities that do not
37 include energy recovery will be examined. Synthetic fibers within scrap tires are not included in this analysis and
38 will be explored for future Inventories. The carbon content of fibers within scrap tires would be used to calculate the
39 associated incineration emissions. Updated fiber content data from the Fiber Economics Bureau will also be
40 explored.

41 **3.4 Coal Mining (IPCC Source Category 1B1a)**

42 Three types of coal mining-related activities release CH₄ to the atmosphere: underground mining, surface mining,
43 and post-mining (i.e., coal-handling) activities. While surface mines account for the majority of U.S. coal
44 production, underground coal mines contribute the largest share of CH₄ emissions (see Table 3-29 and Table 3-30)

⁶⁸ See <<http://unfccc.int/resource/docs/2006/sbsta/eng/09.pdf>>.

⁶⁹ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

1 due to the higher CH₄ content of coal in the deeper underground coal seams. In 2015, 305 underground coal mines
 2 and 529 surface mines were operating in the United States. In recent years the total number of active coal mines in
 3 the United States has declined. In 2015, the United States was the second largest coal producer in the world (812
 4 MMT), after China (3,527 MMT) and followed by India (691 MMT) (IEA 2016).

5 **Table 3-28: Coal Production (kt)**

Year	Underground		Surface		Total	
	Number of Mines	Production	Number of Mines	Production	Number of Mines	Production
1990	1,683	384,244	1,656	546,808	3,339	931,052
2005	586	334,398	789	691,448	1,398	1,025,846
2011	508	313,529	788	684,807	1,296	998,337
2012	488	310,608	719	610,307	1,207	920,915
2013	395	309,546	637	581,270	1,032	890,815
2014	345	321,783	613	583,974	958	905,757
2015	305	278,342	529	534,127	834	812,469

6 Underground mines liberate CH₄ from ventilation systems and from degasification systems. Ventilation systems
 7 pump air through the mine workings to dilute noxious gases and ensure worker safety; these systems can exhaust
 8 significant amounts of CH₄ to the atmosphere in low concentrations. Degasification systems are wells drilled from
 9 the surface or boreholes drilled inside the mine that remove large, often highly concentrated volumes of CH₄ before,
 10 during, or after mining. Some mines recover and use CH₄ generated from ventilation and degasification systems,
 11 thereby reducing emissions to the atmosphere.

12 Surface coal mines liberate CH₄ as the overburden is removed and the coal is exposed to the atmosphere. CH₄
 13 emissions are normally a function of coal rank (a classification related to the percentage of carbon in the coal) and
 14 depth. Surface coal mines typically produce lower-rank coals and remove less than 250 feet of overburden, so their
 15 level of emissions is much lower than from underground mines.

16 In addition, CH₄ is released during post-mining activities, as the coal is processed, transported, and stored for use.

17 Total CH₄ emissions in 2015 were estimated to be 2,436 kt (60.9 MMT CO₂ Eq.), a decline of 37 percent since 1990
 18 (see Table 3-29 and Table 3-30). Of this amount, underground mines accounted for approximately 73 percent,
 19 surface mines accounted for 14 percent, and post-mining emissions accounted for 13 percent.

20 **Table 3-29: CH₄ Emissions from Coal Mining (MMT CO₂ Eq.)**

Activity	1990	2005	2011	2012	2013	2014	2015
Underground (UG) Mining	74.2	42.0	50.2	47.3	46.2	46.4	44.6
Liberated	80.8	59.7	71.0	65.8	64.5	63.1	60.5
Recovered & Used	(6.6)	(17.7)	(20.8)	(18.5)	(18.3)	(16.7)	(15.9)
Surface Mining	10.8	11.9	11.6	10.3	9.7	9.6	8.7
Post-Mining (UG)	9.2	7.6	6.9	6.7	6.6	6.7	5.8
Post-Mining (Surface)	2.3	2.6	2.5	2.2	2.1	2.1	1.9
Total	96.5	64.1	71.2	66.5	64.6	64.8	60.9

Notes: Totals may not sum due to independent rounding. Parentheses indicate negative values.

21 **Table 3-30: CH₄ Emissions from Coal Mining (kt)**

Activity	1990	2005	2011	2012	2013	2014	2015
UG Mining	2,968	1,682	2,008	1,891	1,849	1,854	1,783
Liberated	3,234	2,390	2,839	2,631	2,580	2,523	2,421
Recovered & Used	(266)	(708)	(831)	(740)	(730)	(668)	(638)

Post-Mining (Surface)	93	103	101	89	84	84	75
Total	3,860	2,565	2,849	2,658	2,584	2,593	2,436

Notes: Totals may not sum due to independent rounding. Parentheses indicate negative values.

1 Methodology

2 The methodology for estimating CH₄ emissions from coal mining consists of two steps:

- 3 • Estimate emissions from underground mines. These emissions have two sources: ventilation systems and
4 degasification systems. They are estimated using mine-specific data, then summed to determine total CH₄
5 liberated. The CH₄ recovered and used is then subtracted from this total, resulting in an estimate of net
6 emissions to the atmosphere.
- 7 • Estimate CH₄ emissions from surface mines and post-mining activities. Unlike the methodology for
8 underground mines, which uses mine-specific data, the methodology for estimating emissions from surface
9 mines and post-mining activities consists of multiplying basin-specific coal production by basin-specific gas
10 content and an emission factor.

11 **Step 1: Estimate CH₄ Liberated and CH₄ Emitted from Underground Mines**

12 Underground mines generate CH₄ from ventilation systems and from degasification systems. Some mines recover
13 and use the generated CH₄, thereby reducing emissions to the atmosphere. Total CH₄ emitted from underground
14 mines equals the CH₄ liberated from ventilation systems, plus the CH₄ liberated from degasification systems, minus
15 the CH₄ recovered and used.

16 *Step 1.1: Estimate CH₄ Liberated from Ventilation Systems*

17 To estimate CH₄ liberated from ventilation systems, EPA uses data collected through its Greenhouse Gas Reporting
18 Program (GHGRP) (subpart FF, “Underground Coal Mines”), data provided by the U.S. Mine Safety and Health
19 Administration (MSHA), and occasionally data collected from other sources on a site-specific level (e.g., state gas
20 production databases). Since 2011, the nation’s “gassiest” underground coal mines—those that liberate more than
21 36,500,000 actual cubic feet of CH₄ per year (about 14,700 MT CO₂ Eq.)—have been required to report to EPA’s
22 GHGRP (EPA 2016).⁷⁰ Mines that report to the GHGRP must report quarterly measurements of CH₄ emissions
23 from ventilation systems to EPA; they have the option of recording their own measurements, or using the
24 measurements taken by MSHA as part of that agency’s quarterly safety inspections of all mines in the United States
25 with detectable CH₄ concentrations.⁷¹

26 Since 2013, ventilation emission estimates have been calculated based on both GHGRP data submitted by
27 underground mines, and on quarterly measurement data obtained directly from MSHA for the remaining mines. The
28 quarterly measurements are used to determine the average daily emissions rate for the reporting year quarter.
29 Because not all mines report under the GHGRP, the emissions of the mines that do not report must be calculated
30 using the MSHA data. The MSHA data also serves as a quality assurance tool for validating GHGRP data.

31 *Step 1.2: Estimate CH₄ Liberated from Degasification Systems*

32 Particularly gassy underground mines also use degasification systems (e.g., wells or boreholes) to remove CH₄
33 before, during, or after mining. This CH₄ can then be collected for use or vented to the atmosphere. Twenty-six
34 mines used degasification systems in 2015, and the CH₄ removed through these systems was reported to EPA’s
35 GHGRP (EPA 2016). Based on the weekly measurements reported to EPA’s GHGRP, degasification data
36 summaries for each mine were added together to estimate the CH₄ liberated from degasification systems. Sixteen of

⁷⁰ Underground coal mines report to EPA under Subpart FF of the GHGRP. In 2015, 123 underground coal mines reported to the program.

⁷¹ MSHA records coal mine CH₄ readings with concentrations of greater than 50 ppm (parts per million) CH₄. Readings below this threshold are considered non-detectable.

1 the 26 mines with degasification systems had operational CH₄ recovery and use projects (see step 1.3 below), and
2 GHGRP reports show the remaining ten mines vented CH₄ from degasification systems to the atmosphere.⁷²

3 Degasification volumes for the life of any pre-mining wells are attributed to the mine as emissions in the year in
4 which the well is mined through.⁷³ EPA's GHGRP does not require gas production from virgin coal seams (coalbed
5 methane) to be reported by coal mines under subpart FF. Most pre-mining wells drilled from the surface are
6 considered coalbed methane wells and are reported under another subpart of the program (subpart W, "Petroleum
7 and Natural Gas Systems"). As a result, for the 10 mines with degasification systems that include pre-mining wells,
8 GHGRP information was supplemented with historical data from state gas well production databases (DMME 2016;
9 GSA 2016; WVGES 2016), as well as with mine-specific information regarding the dates on which the pre-mining
10 wells are mined through (JWR 2010; El Paso 2009).

11 Degasification information reported to EPA's GHGRP by underground coal mines was the primary source of data
12 used to develop estimates of CH₄ liberated from degasification systems. Data reported to EPA's GHGRP were used
13 to estimate CH₄ liberated from degasification systems at 21 of the 26 mines that employed degasification systems in
14 2015. For the other five mines (all with pre-mining wells from which CH₄ was recovered), GHGRP data—along
15 with supplemental information from state gas production databases (DMME 2016; GSA 2016; WVGES 2016) —
16 were used to estimate CH₄ liberated from degasification systems. For one mine, due to a lack of mine-provided
17 information used in prior years and a GHGRP reporting discrepancy, the CH₄ liberated was based on both an
18 estimate from historical mine-provided CH₄ recovery and use rates and state gas sales records.

19 *Step 1.3: Estimate CH₄ Recovered from Ventilation and Degasification Systems, and Utilized or* 20 *Destroyed (Emissions Avoided)*

21 Sixteen mines had CH₄ recovery and use projects in place in 2015. Fourteen of these mines sold the recovered CH₄
22 to a pipeline, including one that also used CH₄ to fuel a thermal coal dryer. In addition, one mine used recovered
23 CH₄ for electrical power generation, and one used recovered CH₄ to heat mine ventilation air.

24 Ten of the 16 mines deployed degasification systems in 2015; for those mines, estimates of CH₄ recovered from the
25 systems were exclusively based on GHGRP data. Based on weekly measurements, the GHGRP degasification
26 destruction data summaries for each mine were added together to estimate the CH₄ recovered and used from
27 degasification systems.

28 All 10 mines with degasification systems used pre-mining wells as part of those systems, but only four of them
29 intersected pre-mining wells in 2015. GHGRP and supplemental data were used to estimate CH₄ recovered and used
30 at two of these four mines; supplemental data alone (GSA 2016) were used for the other two mines, which reported
31 to EPA's GHGRP as a single entity. Supplemental information was used for these four mines because estimating
32 CH₄ recovery and use from pre-mining wells requires additional data (not reported under subpart FF of EPA's
33 GHGRP; see discussion in step 1.2 above) to account for the emissions avoided. The supplemental data came from
34 state gas production databases as well as mine-specific information on the timing of mined-through pre-mining
35 wells.

36 GHGRP information was not used to estimate CH₄ recovered and used at two mines. At one of these mines, a
37 portion of reported CH₄ vented was applied to an ongoing mine air heating project. Because of a lack of mine-
38 provided information used in prior years and a GHGRP reporting discrepancy, the 2015 CH₄ recovered and used
39 from pre-mining wells at the other mine was based on an estimate from historical mine-provided CH₄ recovery and
40 use rates. Emissions recovered and used from the active mine degasification system were estimated based on a state
41 gas production data information system.

42 In 2015, one mine destroyed a portion of its CH₄ emissions from ventilation systems using thermal oxidation
43 technology. The amount of CH₄ recovered and destroyed by the project was determined through publicly-available
44 emission reduction project information (ACR 2016).

⁷² Several of the mines venting CH₄ from degasification systems use a small portion the gas to fuel gob well blowers in remote locations where electricity is not available. However, this CH₄ use is not considered to be a formal recovery and use project.

⁷³ A well is "mined through" when coal mining development or the working face intersects the borehole or well.

Step 2: Estimate CH₄ Emitted from Surface Mines and Post-Mining Activities

Mine-specific data are not available for estimating CH₄ emissions from surface coal mines or for post-mining activities. For surface mines, basin-specific coal production obtained from the Energy Information Administration’s Annual Coal Report (EIA 2016) was multiplied by basin-specific CH₄ contents (EPA 1996, 2005) and a 150 percent emission factor (to account for CH₄ from over- and under-burden) to estimate CH₄ emissions (King 1994; Saghafi 2013). For post-mining activities, basin-specific coal production was multiplied by basin-specific gas contents and a mid-range 32.5 percent emission factor for CH₄ desorption during coal transportation and storage (Creedy 1993). Basin-specific *in situ* gas content data were compiled from AAPG (1984) and USBM (1986).

Uncertainty and Time-Series Consistency

A quantitative uncertainty analysis was conducted for the coal mining source category using the IPCC-recommended Approach 2 uncertainty estimation methodology. Because emission estimates from underground ventilation systems were based on actual measurement data from EPA’s GHGRP or from MSHA, uncertainty is relatively low. A degree of imprecision was introduced because the ventilation air measurements used were not continuous but rather quarterly instantaneous readings that were used to determine the average daily emissions rate for the quarter. Additionally, the measurement equipment used can be expected to have resulted in an average of 10 percent overestimation of annual CH₄ emissions (Mutmanský & Wang 2000). GHGRP data were used for a significant number of the mines that reported their own measurements to the program beginning in 2013; however, the equipment uncertainty is applied to both GHGRP and MSHA data.

Estimates of CH₄ recovered by degasification systems are relatively certain for utilized CH₄ because of the availability of GHGRP data and gas sales information. Many of the recovery estimates use data on wells within 100 feet of a mined area. However, uncertainty exists concerning the radius of influence of each well. The number of wells counted, and thus the avoided emissions, may vary if the drainage area is found to be larger or smaller than estimated.

EPA’s GHGRP requires weekly CH₄ monitoring of mines that report degasification systems, and continuous CH₄ monitoring is required for utilized CH₄ on- or off-site. Since 2012, GHGRP data have been used to estimate CH₄ emissions from vented degasification wells, reducing the uncertainty associated with prior MSHA estimates used for this subsource. Beginning in 2013, GHGRP data were also used for determining CH₄ recovery and use at mines without publicly available gas usage or sales records, which has reduced the uncertainty from previous estimation methods that were based on information from coal industry contacts.

In 2015 a level of uncertainty was introduced with the estimated values of recovered methane from two of the mines with degasification systems. An increased level of uncertainty was applied to these two mines, but the change had little impact on the overall uncertainty.

Surface mining and post-mining emissions are associated with considerably more uncertainty than underground mines, because of the difficulty in developing accurate emission factors from field measurements. However, since underground emissions constitute the majority of total coal mining emissions, the uncertainty associated with underground emissions is the primary factor that determines overall uncertainty. The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 3-31. Coal mining CH₄ emissions in 2015 were estimated to be between 53.3 and 70.6 MMT CO₂ Eq. at a 95 percent confidence level. This indicates a range of 12.5 percent below to 15.9 percent above the 2015 emission estimate of 60.9 MMT CO₂ Eq.

Table 3-31: Approach 2 Quantitative Uncertainty Estimates for CH₄ Emissions from Coal Mining (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a (MMT CO ₂ Eq.)			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Coal mining	CH ₄	60.9	53.3	70.6	-12.5%	+15.9%

^a Range of emission estimates predicted by Monte Carlo stochastic simulation for a 95 percent confidence interval.

1 Methodological recalculations were applied to the entire time-series to ensure consistency from 1990 through 2015.
2 Details on the emission trends through time are described in more detail in the methodology section.

3 Recalculations Discussion

4 For the current Inventory, revisions were made to the 2013 and 2014 underground liberated and recovered
5 emissions. In 2014 recovered emissions reported to GHGRP for a mine located in Virginia were too high to be valid.
6 EPA estimated recovered emissions for this mine based on a five-year historical average. In 2016 EPA became
7 aware of the availability of the Virginia Division of Gas and Oil Data Information System (DGO DIS) and was able
8 to estimate recovered degasification emissions for the Virginia mine based on published well production. The well
9 production data was more accurate than the reported values in 2013, 2014, and 2015; thus 2013 and 2014 were
10 revised. The DGO DIS will continue to be used in future years until the GHGRP reported values can be verified for
11 this mine.

12 3.5 Abandoned Underground Coal Mines (IPCC 13 Source Category 1B1a)

14 Underground coal mines contribute the largest share of coal mine methane (CMM) emissions, with active
15 underground mines the leading source of underground emissions. However, mines also continue to release CH₄ after
16 closure. As mines mature and coal seams are mined through, mines are closed and abandoned. Many are sealed and
17 some flood through intrusion of groundwater or surface water into the void. Shafts or portals are generally filled
18 with gravel and capped with a concrete seal, while vent pipes and boreholes are plugged in a manner similar to oil
19 and gas wells. Some abandoned mines are vented to the atmosphere to prevent the buildup of CH₄ that may find its
20 way to surface structures through overburden fractures. As work stops within the mines, CH₄ liberation decreases
21 but it does not stop completely. Following an initial decline, abandoned mines can liberate CH₄ at a near-steady rate
22 over an extended period of time, or, if flooded, produce gas for only a few years. The gas can migrate to the surface
23 through the conduits described above, particularly if they have not been sealed adequately. In addition, diffuse
24 emissions can occur when CH₄ migrates to the surface through cracks and fissures in the strata overlying the coal
25 mine. The following factors influence abandoned mine emissions:

- 26 • Time since abandonment;
- 27 • Gas content and adsorption characteristics of coal;
- 28 • CH₄ flow capacity of the mine;
- 29 • Mine flooding;
- 30 • Presence of vent holes; and
- 31 • Mine seals.

32 Annual gross abandoned mine CH₄ emissions ranged from 7.2 to 10.8 MMT CO₂ Eq. from 1990 through 2015,
33 varying, in general, by less than 1 percent to approximately 19 percent from year to year. Fluctuations were due
34 mainly to the number of mines closed during a given year as well as the magnitude of the emissions from those
35 mines when active. Gross abandoned mine emissions peaked in 1996 (10.8 MMT CO₂ Eq.) due to the large number
36 of gassy mine⁷⁴ closures from 1994 to 1996 (72 gassy mines closed during the three-year period). In spite of this
37 rapid rise, abandoned mine emissions have been generally on the decline since 1996. Since 2002, there have been
38 fewer than twelve gassy mine closures each year. There were six gassy mine closures in 2015. In 2015, gross
39 abandoned mine emissions increased slightly from 8.7 to 9.0 MMT CO₂ Eq. (see Table 3-32 and Table 3-33). Gross
40 emissions are reduced by CH₄ recovered and used at 40 mines, resulting in net emissions in 2015 of 6.4 MMT CO₂
41 Eq.

⁷⁴ A mine is considered a “gassy” mine if it emits more than 100 thousand cubic feet of CH₄ per day (100 mcf/d).

4 Methodology

5 Estimating CH₄ emissions from an abandoned coal mine requires predicting the emissions of a mine from the time
6 of abandonment through the inventory year of interest. The flow of CH₄ from the coal to the mine void is primarily
7 dependent on the mine's emissions when active and the extent to which the mine is flooded or sealed. The CH₄
8 emission rate before abandonment reflects the gas content of the coal, the rate of coal mining, and the flow capacity
9 of the mine in much the same way as the initial rate of a water-free conventional gas well reflects the gas content of
10 the producing formation and the flow capacity of the well. A well or a mine which produces gas from a coal seam
11 and the surrounding strata will produce less gas through time as the reservoir of gas is depleted. Depletion of a
12 reservoir will follow a predictable pattern depending on the interplay of a variety of natural physical conditions
13 imposed on the reservoir. The depletion of a reservoir is commonly modeled by mathematical equations and mapped
14 as a type curve. Type curves which are referred to as decline curves have been developed for abandoned coal mines.
15 Existing data on abandoned mine emissions through time, although sparse, appear to fit the hyperbolic type of
16 decline curve used in forecasting production from natural gas wells.

17 In order to estimate CH₄ emissions over time for a given abandoned mine, it is necessary to apply a decline function,
18 initiated upon abandonment, to that mine. In the analysis, mines were grouped by coal basin with the assumption
19 that they will generally have the same initial pressures, permeability and isotherm. As CH₄ leaves the system, the
20 reservoir pressure (Pr) declines as described by the isotherm's characteristics. The emission rate declines because
21 the mine pressure (Pw) is essentially constant at atmospheric pressure for a vented mine, and the productivity index
22 (PI), which is expressed as the flow rate per unit of pressure change, is essentially constant at the pressures of
23 interest (atmospheric to 30 psia). The CH₄ flow rate is determined by the laws of gas flow through porous media,
24 such as Darcy's Law. A rate-time equation can be generated that can be used to predict future emissions. This
25 decline through time is hyperbolic in nature and can be empirically expressed as:

$$26 \quad q = q_i (1 + bD_i t)^{-1/b}$$

27 where,

28	q	=	Gas flow rate at time t in million cubic feet per day (mmcf/d)
29	q _i	=	Initial gas flow rate at time zero (t ₀), mmcf/d
30	b	=	The hyperbolic exponent, dimensionless
31	D _i	=	Initial decline rate, 1/yr
32	t	=	Elapsed time from t ₀ (years)

33 This equation is applied to mines of various initial emission rates that have similar initial pressures, permeability and
34 adsorption isotherms (EPA 2004).

The decline curves created to model the gas emission rate of coal mines must account for factors that decrease the rate of emissions after mining activities cease, such as sealing and flooding. Based on field measurement data, it was assumed that most U.S. mines prone to flooding will become completely flooded within eight years and therefore will no longer have any measurable CH₄ emissions. Based on this assumption, an average decline rate for flooded mines was established by fitting a decline curve to emissions from field measurements. An exponential equation was developed from emissions data measured at eight abandoned mines known to be filling with water located in two of the five basins. Using a least squares, curve-fitting algorithm, emissions data were matched to the exponential equation shown below. There was not enough data to establish basin-specific equations as was done with the vented, non-flooding mines (EPA 2004).

$$q = q_i e^{-Dt}$$

where,

q	=	Gas flow rate at time t in mmcf/d
q _i	=	Initial gas flow rate at time zero (t ₀), mmcf/d
D	=	Decline rate, 1/yr
t	=	Elapsed time from t ₀ (years)

Seals have an inhibiting effect on the rate of flow of CH₄ into the atmosphere compared to the flow rate that would exist if the mine had an open vent. The total volume emitted will be the same, but emissions will occur over a longer period of time. The methodology, therefore, treats the emissions prediction from a sealed mine similarly to the emissions prediction from a vented mine, but uses a lower initial rate depending on the degree of sealing. A computational fluid dynamics simulator was used with the conceptual abandoned mine model to predict the decline curve for inhibited flow. The percent sealed is defined as 100 × (1 – [initial emissions from sealed mine / emission rate at abandonment prior to sealing]). Significant differences are seen between 50 percent, 80 percent and 95 percent closure. These decline curves were therefore used as the high, middle, and low values for emissions from sealed mines (EPA 2004).

For active coal mines, those mines producing over 100 thousand cubic feet per day (mcf/d) account for about 98 percent of all CH₄ emissions. This same relationship is assumed for abandoned mines. It was determined that the 524 abandoned mines closed after 1972 produced emissions greater than 100 mcf/d when active. Further, the status of 302 of the 524 mines (or 58 percent) is known to be either: 1) vented to the atmosphere; 2) sealed to some degree (either earthen or concrete seals); or, 3) flooded (enough to inhibit CH₄ flow to the atmosphere). The remaining 42 percent of the mines whose status is unknown were placed in one of these three categories by applying a probability distribution analysis based on the known status of other mines located in the same coal basin (EPA 2004).

Table 3-34: Number of Gassy Abandoned Mines Present in U.S. Basins in 2015, grouped by Class according to Post-Abandonment State

Basin	Sealed	Vented	Flooded	Total		Total Mines
				Known	Unknown	
Central Appl.	40	26	52	118	143	261
Illinois	34	3	14	51	30	81
Northern Appl.	46	22	16	84	39	123
Warrior Basin	0	0	16	16	0	16
Western Basins	28	3	2	33	10	43
Total	148	54	100	302	222	524

Inputs to the decline equation require the average emission rate and the date of abandonment. Generally this data is available for mines abandoned after 1971; however, such data are largely unknown for mines closed before 1972. Information that is readily available, such as coal production by state and county, is helpful but does not provide enough data to directly employ the methodology used to calculate emissions from mines abandoned before 1972. It is assumed that pre-1972 mines are governed by the same physical, geologic, and hydrologic constraints that apply to post-1971 mines; thus, their emissions may be characterized by the same decline curves.

During the 1970s, 78 percent of CH₄ emissions from coal mining came from seventeen counties in seven states. In addition, mine closure dates were obtained for two states, Colorado and Illinois, for the hundred year period extending from 1900 through 1999. The data were used to establish a frequency of mine closure histogram (by

decade) and applied to the other five states with gassy mine closures. As a result, basin-specific decline curve equations were applied to the 145 gassy coal mines estimated to have closed between 1920 and 1971 in the United States, representing 78 percent of the emissions. State-specific, initial emission rates were used based on average coal mine CH₄ emissions rates during the 1970s (EPA 2004).

Abandoned mine emission estimates are based on all closed mines known to have active mine CH₄ ventilation emission rates greater than 100 mcf/d at the time of abandonment. For example, for 1990 the analysis included 145 mines closed before 1972 and 258 mines closed between 1972 and 1990. Initial emission rates based on MSHA reports, time of abandonment, and basin-specific decline curves influenced by a number of factors were used to calculate annual emissions for each mine in the database (MSHA 2016). Coal mine degasification data are not available for years prior to 1990, thus the initial emission rates used reflect ventilation emissions only for pre-1990 closures. CH₄ degasification amounts were added to the quantity of CH₄ vented to determine the total CH₄ liberation rate for all mines that closed between 1992 and 2015. Since the sample of gassy mines is assumed to account for 78 percent of the pre-1972 and 98 percent of the post-1971 abandoned mine emissions, the modeled results were multiplied by 1.22 and 1.02 to account for all U.S. abandoned mine emissions.

From 1993 through 2015, emission totals were downwardly adjusted to reflect abandoned mine CH₄ emissions avoided from those mines. The Inventory totals were not adjusted for abandoned mine reductions from 1990 through 1992 because no data was reported for abandoned coal mining CH₄ recovery projects during that time.

Uncertainty and Time-Series Consistency

A quantitative uncertainty analysis was conducted to estimate the uncertainty surrounding the estimates of emissions from abandoned underground coal mines. The uncertainty analysis described below provides for the specification of probability density functions for key variables within a computational structure that mirrors the calculation of the inventory estimate. The results provide the range within which, with 95 percent certainty, emissions from this source category are likely to fall.

As discussed above, the parameters for which values must be estimated for each mine in order to predict its decline curve are: 1) the coal's adsorption isotherm; 2) CH₄ flow capacity as expressed by permeability; and 3) pressure at abandonment. Because these parameters are not available for each mine, a methodological approach to estimating emissions was used that generates a probability distribution of potential outcomes based on the most likely value and the probable range of values for each parameter. The range of values is not meant to capture the extreme values, but rather values that represent the highest and lowest quartile of the cumulative probability density function of each parameter. Once the low, mid, and high values are selected, they are applied to a probability density function.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 3-35. Annual abandoned coal mine CH₄ emissions in 2015 were estimated to be between 5.2 and 7.9 MMT CO₂ Eq. at a 95 percent confidence level. This indicates a range of 18 percent below to 24 percent above the 2015 emission estimate of 6.4 MMT CO₂ Eq. One of the reasons for the relatively narrow range is that mine-specific data is available for use in the methodology for mines closed after 1972. Emissions from mines closed prior to 1972 have the largest degree of uncertainty because no mine-specific CH₄ liberation rates exist.

Table 3-35: Approach 2 Quantitative Uncertainty Estimates for CH₄ Emissions from Abandoned Underground Coal Mines (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a (MMT CO ₂ Eq.)			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Abandoned Underground Coal Mines	CH ₄	6.4	5.2	7.9	-18%	+24%

^a Range of emission estimates predicted by Monte Carlo Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

3.6 Petroleum Systems (IPCC Source Category 1B2a)

EPA is seeking stakeholder feedback on a number of options for updating the emissions estimates in this section. See Recalculations Discussion below for methods used in the development of the public review draft, and EPA's memos on updates under consideration for other options being considered: <https://www.epa.gov/ghgemissions/updates-under-consideration-petroleum-and-natural-gas-systems-1990-2015-ghg-inventory>. It is likely that the methods presented here and the calculated emissions totals will change due to revisions between this public review draft of the 1990-2015 Inventory and the final 1990-2015 Inventory, but impacts on the total emissions estimate are expected to be minor. See the recalculations discussion below for more details. Note that 2014 results for CO₂ emissions are being used as a preliminary estimate for 2015 while EPA reviews the activity data and estimation methods for consistency with data sources used for methane calculations.

Methane emissions from petroleum systems are primarily associated with onshore and offshore crude oil production, transportation, and refining operations. During these activities, CH₄ is released to the atmosphere as fugitive emissions, vented emissions, emissions from operational upsets, and emissions from fuel combustion. Fugitive and vented CO₂ emissions from petroleum systems are primarily associated with crude oil production and refining operations but are negligible in transportation operations. Total CH₄ emissions from petroleum systems in 2015 were 41.5 MMT CO₂ Eq. (1,660 kt). Total CO₂ emissions from petroleum systems in 2015 were 3.0 MMT CO₂ Eq. (3,041 kt).

Production Field Operations. Production field operations account for approximately 98 percent of total CH₄ emissions from petroleum systems. Vented CH₄ from field operations account for approximately 85 percent of the net emissions from the production sector, fugitive emissions are approximately 7 percent, uncombusted CH₄ emissions (i.e., unburned fuel) account for approximately 8 percent, and process upset emissions are 0.2 percent. The predominant sources of emissions from production field operations are pneumatic controllers, offshore oil platforms, associated gas venting and flaring, oil tanks, gas engines, chemical injection pumps, hydraulically fractured oil well completions, and oil wellheads. These sources alone emit over 90 percent of the production field operations emissions. The remaining 10 percent of the emissions are distributed among around 20 additional activities.

Since 1990, CH₄ emissions from production field operations have decreased by nearly 30 percent. Production segment methane emissions have decreased by around 8 percent from 2014 levels, primarily due to decreases in emissions from associated gas venting and flaring.

Vented CO₂ associated with production field operations account for approximately 99 percent of the total CO₂ emissions from production field operations, while fugitive and process upsets together account for approximately 1 percent of the emissions. The principal sources of CO₂ emissions are oil tanks, pneumatic controllers, chemical injection pumps, and offshore oil platforms. These four sources together account for slightly over 97 percent of the non-combustion CO₂ emissions from production field operations, while the remaining 3 percent of the emissions is distributed among around 20 additional activities. Due to the activity data source for CO₂ from flaring, it is not possible to develop separate estimates for flaring occurring in natural gas production and flaring occurring in oil production. Total CO₂ emissions from flaring for both natural gas and oil were 18.0 MMT CO₂ in 2015 and are included in the Natural Gas Systems estimates.

Crude Oil Transportation. Crude oil transportation activities account for approximately 1 percent of total CH₄ emissions from the oil industry. Venting emissions, including from tanks, truck loading, rail loading, and marine vessel loading operations account for 89 percent of CH₄ emissions from crude oil transportation. Fugitive emissions, almost entirely from floating roof tanks, account for approximately 11 percent of CH₄ emissions from crude oil transportation.

Since 1990, CH₄ emissions from transportation have increased by 28 percent. However, because emissions from crude oil transportation account for such a small percentage of the total emissions from the petroleum industry, this has had little impact on the overall emissions. Methane emissions from transportation in 2015 increased by approximately 2 percent from 2014 levels.

1 *Crude Oil Refining.* Crude oil refining processes and systems account for approximately 2 percent of total CH₄
 2 emissions from the oil industry because most of the CH₄ in crude oil is removed or escapes before the crude oil is
 3 delivered to the refineries. There is an insignificant amount of CH₄ in all refined products. Within refineries,
 4 incomplete combustion accounts for slightly over 51 percent of the CH₄ emissions, while vented and fugitive
 5 emissions account for approximately 34 and 15 percent, respectively. Flaring accounts for 82 percent of combustion
 6 CH₄ emissions. Refinery system blowdowns for maintenance and process vents are the primary venting contributors
 7 (97 percent). Most of the fugitive CH₄ emissions from refineries are from equipment leaks and storage tanks (87
 8 percent).

9 Methane emissions from refining of crude oil have increased by approximately 7 percent since 1990; however,
 10 similar to the transportation subcategory, this increase has had little effect on the overall emissions of CH₄. Since
 11 1990, CH₄ emissions from crude oil refining have fluctuated between 24 and 28 kt.

12 Flare emissions from crude oil refining accounts for slightly more than 93 percent of the total CO₂ emissions in
 13 petroleum systems. Refinery CO₂ emissions increased by approximately 9 percent from 1990 to 2015.

2 Methodology

3 The estimates of CH₄ emissions from petroleum systems are largely based on GRI/EPA 1996, EPA 1999,
4 DrillingInfo, and EPA's GHGRP data (RY 2010 through 2015). Petroleum Systems includes emission estimates for
5 activities occurring in petroleum systems from the oil wellhead through crude oil refining, including activities for
6 crude oil production field operations, crude oil transportation activities, and refining operations. Annex 3.5 provides
7 detail on the emission estimates for these activities. The estimates of CH₄ emissions from petroleum systems do not
8 include emissions downstream of oil refineries because these emissions are considered to be negligible.

9 Emissions are estimated for each activity by multiplying emission factors (e.g., emission rate per equipment or per
10 activity) by the corresponding activity data (e.g., equipment count or frequency of activity).

11 References for emission factors include *Methane Emissions from the Natural Gas Industry by the Gas Research*
12 *Institute and EPA* (EPA/GRI 1996a-d), *Estimates of Methane Emissions from the U.S. Oil Industry* (EPA 1999),
13 DrillingInfo (2015), consensus of industry peer review panels, BOEMRE and BOEM reports (BOEMRE 2004;
14 BOEM 2011), analysis of BOEMRE data (EPA 2005; BOEMRE 2004), and the GHGRP (2010 through 2015).

15 The emission factors for pneumatic controllers venting and chemical injection pumps were developed using EPA's
16 GHGRP data for reporting year 2014. The emission factors for tanks, and associated gas venting and flaring were
17 developed using EPA's GHGRP data for reporting year 2015. Emission factors for hydraulically fractured (HF) oil
18 well completions (controlled and uncontrolled) were developed using data analyzed for the 2015 NSPS OOOOa
19 proposal (EPA 2015a). For offshore oil production, two emission factors were calculated using data collected for all
20 federal offshore platforms (EPA 2015b; BOEM 2014), one for oil platforms in shallow water, and one for oil
21 platforms in deep water. For all sources, emission factors are held constant for the period 1990 through 2015.
22 Emission factors from EPA 1999 are used for all other production and transportation activities.

23 References for activity data include DrillingInfo (2016), the Energy Information Administration annual and monthly
24 reports (EIA 1990 through 2016), (EIA 1995 through 2016a, 2016b), *Methane Emissions from the Natural Gas*
25 *Industry by the Gas Research Institute and EPA* (EPA/GRI 1996a-d), *Estimates of Methane Emissions from the U.S.*

1 *Oil Industry* (EPA 1999), consensus of industry peer review panels, BOEMRE and BOEM reports (BOEMRE 2004;
2 BOEM 2011), analysis of BOEMRE data (EPA 2005; BOEMRE 2004), the Oil & Gas Journal (OGJ 2016), the
3 Interstate Oil and Gas Compact Commission (IOGCC 2012), the United States Army Corps of Engineers, (1995
4 through 2016), and the GHGRP (2010 through 2015).

5 For many sources, complete activity data were not available for all years of the time series. In such cases, one of
6 three approaches was employed to estimate values, consistent with IPCC good practice. Where appropriate, the
7 activity data were calculated from related statistics using ratios developed based on EPA 1996, and/or GHGRP data.
8 For floating roof tanks, the activity data were held constant from 1990 through 2015 based on EPA (1999). In some
9 cases, activity data are developed by interpolating between recent data points (such as from GHGRP) and earlier
10 data points, such as from GRI 1996. Lastly, the previous year's data were used for domestic barges and tankers as
11 current year were not yet available. For offshore production, the number of platforms in shallow water and the
12 number of platforms in deep water are used as activity data and are taken from Bureau of Ocean Energy
13 Management (BOEM) (formerly Bureau of Ocean Energy Management, Regulation, and Enforcement [BOEMRE])
14 datasets (BOEM 2011a,b,c).

15 For petroleum refining activities, 2010 to 2015 emissions were directly obtained from EPA's GHGRP. All U.S.
16 refineries have been required to report CH₄ and CO₂ emissions for all major activities starting with emissions that
17 occurred in 2010. The national totals of these emissions for each activity were used for the 2010 to 2015 emissions.
18 The national emission totals for each activity were divided by refinery feed rates for those inventory years to
19 develop average activity-specific emission factors, which were used to estimate national emissions for each refinery
20 activity from 1990 to 2009 based on national refinery feed rates for each year (EPA 2015c).

21 The inventory estimate for Petroleum Systems takes into account Natural Gas STAR reductions. Voluntary
22 reductions included in the Petroleum Systems calculations were those reported to Natural Gas STAR for the
23 following activities: artificial lift - gas lift; artificial lift - use compression; artificial lift - use pumping unit;
24 consolidate crude oil production and water storage tanks; lower heater-treater temperature; re-inject gas for
25 enhanced oil recovery; re-inject gas into crude; and route casinghead gas to vapor recovery unit or compressor.

26 The methodology for estimating CO₂ emissions from petroleum systems includes calculation of vented, fugitive, and
27 process upset emissions sources from 26 activities for crude oil production field operations and three activities from
28 petroleum refining. Generally, emissions are estimated for each activity by multiplying CO₂ emission factors by
29 their corresponding activity data. The production field operations emission factors for CO₂ are generally estimated
30 by multiplying the CH₄ emission factors by a conversion factor, which is the ratio of CO₂ content and CH₄ content
31 in produced associated gas. One exception to this methodology are emission factors for offshore oil production
32 (shallow and deep water), which were derived using data from BOEM (EPA 2015b; BOEM 2014). For the three
33 petroleum refining activities (i.e., flares, asphalt blowing, and process vents); the CO₂ emissions data for 2010 to
34 2014 were directly obtained from the GHGRP. The 2010 to 2013 CO₂ emissions data from GHGRP along with the
35 refinery feed data for 2010 to 2013 were used to derive CO₂ emission factors (i.e., sum of activity emissions/sum of
36 refinery feed) which were then applied to the annual refinery feed to estimate CO₂ emissions for 1990 to 2009.

37 **Uncertainty and Time-Series Consistency**

38 EPA's planned uncertainty analysis is discussed in the Planned Improvements section.

39 New data available starting in 2010 for refineries and in 2011 for other sources have improved estimates of
40 emissions from Petroleum Systems. Many of the previously available data sets were collected in the 1990s. To
41 develop a consistent time series for 1990-2015, for sources with new data, EPA reviewed available information on
42 factors that may have resulted in changes over the time series (e.g. regulations, voluntary actions) and requested
43 stakeholder feedback on trends as well. For most sources, EPA developed annual data for 1993-2010 by
44 interpolating activity data or emission factors or both between 1992 and 2011 data points.

45 Information on time-series consistency for sources updated in this public review draft can be found in the
46 Recalculation Discussion below, with additional detail provided in the 2017 Production Memo. For information on
47 other sources, please see the Methodology Discussion above.

1 QA/QC and Verification Discussion

2 The petroleum system emission estimates in the Inventory are continually being reviewed and assessed to determine
3 whether emission factors and activity factors accurately reflect current industry practices. A QA/QC analysis was
4 performed for data gathering and input, documentation, and calculation. QA/QC checks are consistently conducted
5 to minimize human error in the model calculations. EPA performs a thorough review of information associated with
6 new studies, GHGRP data, regulations, public webcasts, and the Natural Gas STAR Program to assess whether the
7 assumptions in the Inventory are consistent with current industry practices. The EPA has a multi-step data
8 verification process for GHGRP data, including automatic checks during data-entry, statistical analyses on
9 completed reports, and staff review of the reported data. Based on the results of the verification process, the EPA
10 follows up with facilities to resolve mistakes that may have occurred.

11 As in previous years, EPA conducted early engagement and communication with stakeholders on updates prior to
12 public review. In December 2016 and January 2017, EPA stakeholder webinars on GHG data for oil and gas. In
13 early 2017, EPA released memos detailing updates under consideration and requesting stakeholder feedback. EPA
14 discusses preliminary stakeholder feedback received in the public review draft. EPA continues to receive and review
15 feedback on the options presented, and may revise the recalculations in the final 1990-2015 Inventory based on that
16 feedback.

17 In recent years, several studies have measured emissions at the source level and at the national or regional level and
18 calculated emissions estimates that may differ from the GHG Inventory. There are a variety of potential uses of data
19 from new studies, including replacing a previous estimate or factor, verifying or QA of an existing estimate or
20 factor, and identifying areas for updates.

21 In general, there are two major types of studies related to oil and gas greenhouse gas data: studies that focus on
22 measurement or quantification of emissions from specific activities, processes and equipment, and studies that focus
23 on verification of estimates through inverse modeling. The first type of study can lead to direct improvements to or
24 verification of GHG Inventory estimates. In the past few years, EPA has reviewed and in many cases, incorporated
25 data from these data sources. The second type of study can provide general indications on potential over- and
26 under-estimates. A key challenge in using these types of studies to assess GHG Inventory results is having a relevant
27 basis for comparison. In an effort to improve the ability to compare the national-level GHG inventory with
28 measurement results that may be at other scales, a team at Harvard University along with EPA and other coauthors
29 developed a gridded inventory of U.S. anthropogenic methane emissions with 0.1° x 0.1° spatial resolution, monthly
30 temporal resolution, and detailed scale-dependent error characterization.⁷⁵ The inventory is designed to be
31 consistent with the 2016 U.S. EPA *Inventory of U.S. Greenhouse Gas Emissions and Sinks (1990-2014)* estimates
32 for the year 2012, which presents national totals for different source types.⁷⁶

33 Recalculations Discussion

34 The EPA received information and data related to the emission estimates through the Inventory preparation process,
35 previous Inventories' formal public notice periods, GHGRP reporting, and new studies. The EPA carefully
36 evaluated relevant information available, and made updates to the production segment methodology for this public
37 review draft of the Inventory including revised well count, equipment count, and pneumatic controller activity data,
38 and revised activity and emissions data for tanks and associated gas venting and flaring.

39 In January 2017, the EPA released a draft memorandum, *Inventory of U.S. Greenhouse Gas Emissions and Sinks*
40 *1990-2014: Revisions under Consideration for Natural Gas and Petroleum Systems Production Emissions*, referred
41 to below as "2017 Production Memo," that discussed the changes under consideration and requested stakeholder
42 feedback on those changes.⁷⁷ In this public review draft of the Inventory, EPA has selected from the options
43 presented in the 2017 Production Memo to develop emissions estimates. EPA continues to receive and review

⁷⁵ See <<https://www.epa.gov/ghgemissions/gridded-2012-methane-emissions>>.

⁷⁶ See <<https://www.epa.gov/ghgemissions/us-greenhouse-gas-inventory-report-1990-2014>>.

⁷⁷ See <https://www.epa.gov/sites/production/files/2017-01/documents/2017_ghgi_ngpetro_revunderconsideration_and_gb_1.10.17.pdf>.

1 feedback on the options presented, and it is likely that the methods presented here and the calculated emissions totals
 2 will change due to revisions between this public review draft of the 2017 GHG Inventory (1990-2015) and the final
 3 2017 GHG Inventory, but impacts on the total emissions estimate are expected to be minor.

4 The combined impact of revisions to 2014 petroleum production segment emissions, compared to the previous
 5 Inventory, is a decrease in CH₄ emissions from 67.4 to 44.1 MMT CO₂ Eq. (23 MMT CO₂ Eq., or 35 percent).

6 The recalculations resulted in an average increase in emission estimates across the 1990 through 2014 time series,
 7 compared to the previous Inventory, of 3.2 MMT CO₂ Eq., or 7 percent. The recalculations resulted in increases in
 8 the emission estimate in early years of the time series, primarily due to recalculations related to associated gas
 9 venting and flaring, and decreases in the emission estimate in later years of the time series, primarily due to
 10 recalculations for pneumatic controllers.

11 **Production**

12 This section references the memorandum, *Inventory of U.S. Greenhouse Gas Emissions and Sinks 1990-2015:*
 13 *Revisions under Consideration for Natural Gas and Petroleum Systems Production Emissions* (2017 Production
 14 Memo). This memorandum contains further details and documentation of recalculations.

15 *Well Counts*

16 EPA has used a more recent version of the DrillingInfo data set to update well counts data in this public review draft
 17 of the Inventory. For more information, see pages 19 through 20 of the 2017 Production Memo. This update
 18 resulted in a decrease of 34 percent in oil well counts on average over the time series. EPA received feedback that
 19 stakeholders generally support the revision as introducing more consistency with recently published well count
 20 estimates. EPA continues to compare current estimates with stakeholder well counts also derived from DrillingInfo,
 21 investigate differences, and may further revise the well count estimates in the final Inventory, potentially resulting in
 22 additional (but likely minor) decreases in calculated emissions from sources that rely on oil well counts for activity
 23 data (e.g., pneumatic controllers, equipment leaks, and storage tanks).

24

25 **Table 3-40: Oil Well Count Data**

Oil Well Count	1990	2005	2011	2012	2013	2014	2015
Number of Oil Wells	595,109	497,744	560,005	584,515	601,670	619,818	607,559
<i>Previous Estimated Number of Oil Wells</i>	<i>904,675</i>	<i>764,371</i>	<i>838,899</i>	<i>867,375</i>	<i>884,652</i>	<i>898,268</i>	<i>NA</i>
Percent Change in Counts	-34%	-35%	-33%	-33%	-32%	-31%	NA

NA – Not Applicable

26 *Tanks*

27 In the public review draft, EPA developed emissions estimates for oil tanks using GHGRP data and an equipment-
 28 based approach. For more information, please see pages 5 through 14 of the 2017 Production Memo. Using 2015
 29 GHGRP data, EPA developed a value for the number of large tanks per well (0.54) and the number of small tanks
 30 per well (0.21), a fraction of tanks in each of five categories (large tanks with flares, large tanks with VRU,
 31 uncontrolled large tanks, small tanks with flares, and small tanks without flares) for 2015, and corresponding
 32 emission factors. The count of large and small tanks per well of 0.54 and 0.21, respectively, was applied to total oil
 33 well counts for each year of the time series. The 2015 fraction of tanks in each control category was applied to tanks
 34 for the years 2011 to 2015. For 1990, it was assumed that all tanks were in the uncontrolled categories. EPA then
 35 linearly interpolated from 1990 to 2011 for each category. Category-specific emission factors developed from 2015
 36 GHGRP data were applied for each year of the time series. EPA also developed a per-tank emission factor for
 37 malfunctioning dump valves. In the GHGRP, only large tanks report malfunctioning dump valves. EPA has applied
 38 the emission factor to all large tanks for each year of the time series. EPA received some initial stakeholder feedback
 39 on the updates under consideration for this source suggesting that the GHGRP methods for tanks could result in
 40 potential underestimates in reported emissions, while other feedback suggested the GHGRP methods did not
 41 underestimate tank emissions. EPA also received feedback from two commenters supporting the throughput-based

1 approach over the tank count based approach (approach used here), noting that throughput more directly relates to
 2 tank emission than the number of tanks. Based on this initial feedback, EPA is considering using the throughput-
 3 based approach for the final 2017 GHG inventory. The throughput-based approach would result in lower national
 4 methane emissions than the tank-based approach, with 2014 oil tank emissions around 50 percent lower than
 5 emissions calculated using the tank-based approach presented here. As noted above, EPA continues to receive and
 6 review feedback on the options presented and will also assess information received as public review comments.

7 **Table 3-41: National Tank Activity Data (Number of Tanks) by Category and National**
 8 **Emissions (Metric Tons CH₄)**

Activity Data/Emissions	1990	2005	2011	2012	2013	2014	2015
Large Tanks w/ Flares (Counts)	0	112,752	177,597	185,370	190,811	196,566	192,679
Large Tanks w/ VRU (Counts)	0	19,083	30,058	31,374	32,294	33,269	32,611
Large Tanks w/o Control (Counts)	319,160	135,108	92,678	96,734	99,573	102,577	100,548
Small Tanks w/ Flares (Counts)	0	18,349	28,902	30,167	31,052	31,989	31,356
Small Tanks w/o Flares (Counts)	126,204	87,207	89,858	93,791	96,543	99,455	97,488
Total Emissions (MT)	335,031	160,949	127,406	132,983	136,885	141,014	138,225

Percent Change in Emissions	34%	-14%	-42%	-52%	-59%	-64%	NA

NA – Not Applicable

9 *Equipment Counts (Fugitive Sources)*

10 Additional reporting to GHGRP for RY2015 improved EPA's allocation of GHGRP equipment counts between
 11 natural gas and petroleum for certain equipment leak category sources. EPA used the RY2015 reporting data to
 12 develop improved counts of equipment per well. For more information, please see pages 20 through 22 of the 2017
 13 Production Memo. For the public review draft, EPA developed per well counts using 2015 GHGRP and applied
 14 those to national oil well counts for years 2011 through 2015. The per well counts for 1990 through 1992 were
 15 retained from previous inventories, and counts for 1993 through 2010 were developed by linear interpolation.
 16 Overall, the change decreased calculated emissions over the time series by around 12 percent, with the largest
 17 changes in light crude separators.

18 **Table 3-42: National Equipment Counts for Fugitive Sources and National Emissions (Metric**
 19 **Tons CH₄)**

Activity Data/Emissions	1990	2005	2011	2012	2013	2014	2015
Separators (Heavy Crude) (Counts)	12,575	18,730	22,047	23,011	23,687	24,401	23,919
Separators (Light Crude) (Counts)	114,447	170,459	200,646	209,428	215,574	222,076	217,684
Heater/Treaters (Light Crude) (Counts)	87,106	115,283	131,084	136,821	140,837	145,085	142,215
Headers (Heavy Crude) (Counts)	15,523	26,937	32,909	34,350	35,358	36,424	35,704
Headers (Light Crude) (Counts)	48,124	83,508	102,023	106,488	109,613	112,920	110,686
Total Emissions (MT)	26,593	38,563	45,054	47,026	48,406	49,866	48,880

Percent Change in Emissions	-6%	-15%	-17%	-16%	-15%	-14%	NA

NA – Not Applicable

20 *Pneumatic Controllers and Chemical Injection Pumps*

21 The changes to pneumatic controller and chemical injection pump equipment counts result from the changes in oil
 22 well counts described above and from the improved estimate of the counts of oil wells in GHGRP, which improved
 23 the activity factors of counts of controllers and pumps per oil well. The total per well counts of pneumatic
 24 controllers and pumps were updated using year 2015 GHGRP data. These per well counts were applied to years

2011 through 2015. For years 2011 through 2015, GHGRP year-specific data on fractions of pneumatic controllers in each category (high bleed “HB”, low bleed “LB”, and intermittent “IB”) were applied to the counts of pneumatic controllers. The 1990 through 1992 per well counts of controllers in each category and pumps were retained for 1990 through 1992 and then the per well counts of pneumatic controllers in each category for 1993 through 2010 were developed by linearly interpolating from 1992 through 2011. Category-specific emissions factors developed for the previous Inventory from year 2014 GHGRP data were applied throughout the time series. The recalculations resulted in large decreases in total national counts, but only minor changes in the annual fractions of controllers in each category.

Table 3-43: Pneumatic Controller and Chemical Injection Pump National Equipment Counts and National Emissions (Metric Tons CH₄)

Activity Data/Emissions	1990	2005	2011	2012	2013	2014	2015

Associated Gas Venting and Flaring

EPA developed a new estimate for associated gas venting and flaring, replacing its previous estimates for stripper well venting. For more information, please see pages 14 through 19 of the 2017 Production Memo. For the public review draft, EPA developed a total percentage of oil wells that vent and flare from 2015 GHGRP data (12 percent), and applied that value to total national oil well counts for full time series. EPA then applied the GHGRP year-specific split of that 12 percent between venting wells and flaring wells for years 2011 to 2015, and applied the 2011 split to each year from 1990 to 2011. Emission factors developed from year 2015 GHGRP data were applied for the full time series. EPA then removed the “stripper well” line item that had been included in previous inventories as those emissions are included in the updated estimates for associated gas venting and flaring.

Table 3-44: Associated Gas Well Venting and Flaring National Emissions (Metric Tons CH₄)

1 *Transportation*

2 Recalculations due to updated activity data for quantity of petroleum transported by barge or tanker in the
3 transportation segment have resulted in an average increase in calculated emissions over the time series from this
4 segment of less than 0.01 percent.

5 *Refining*

6 Recalculations due to updated data, including resubmitted GHGRP data, in the refining segment have resulted in an
7 average increase in calculated emissions over the time series from this segment of less than 0.01 percent.

8 **Planned Improvements**

9 **Plans for Final 2017 GHG Inventory**

10 EPA continues to receive and review stakeholder feedback on the 2017 Production Memo. EPA will consider this
11 feedback, along with feedback on this public review draft as it develops the final Inventory.

12 EPA seeks feedback on the methods applied in this public review draft, on other options presented in the 2017
13 Production Memo, and on additional planned improvements under consideration discussed in this section.

14 *Uncertainty*

15 The most recent uncertainty analysis for the petroleum systems emission estimates in the Inventory was conducted
16 for the 1990 to 2009 Inventory that was released in 2011. Since the analysis was last conducted, several of the
17 methods used in the Inventory have changed, and industry practices and equipment have evolved. In addition, new
18 studies and other data sources such as those discussed in the sections below offer improvement to understanding and
19 quantifying the uncertainty of some emission source estimates. EPA is planning for the final Inventory an update to
20 the uncertainty analysis conducted for the Inventory published in 2011 to reflect the new information. It is difficult
21 to project whether updated uncertainty bounds around CH₄ emission estimates would be wider, tighter, or about the
22 same as the current uncertainty bounds that were developed for the Inventory published in 2011 (i.e., minus 24
23 percent and plus 149 percent).

24 *Gas STAR Reductions in Petroleum Systems Production Segment*

25 The Inventory estimate for Petroleum Systems takes into account reductions reported to the Natural Gas STAR
26 program.⁷⁸ Reductions included in the Petroleum Systems calculations are those reported to Natural Gas STAR for
27 the following activities: artificial lift - gas lift; artificial lift - use compression; artificial lift - use pumping unit;
28 consolidate crude oil production and water storage tanks; lower heater-treater temperature; re-inject gas for
29 enhanced oil recovery; re-inject gas into crude; and route casinghead gas to vapor recovery unit or compressor.

30 EPA is considering removing the Gas STAR reductions from its calculations for the Petroleum Systems Production
31 segment. In this public review draft of the Inventory, Gas STAR petroleum systems reductions reduce calculated
32 potential emissions by an average of 1 percent over the times series. Many emissions sources in the Inventory are
33 now calculated using net emissions approaches, with technology-specific activity data and emission factors, and
34 annual data from the GHGRP. It may not be necessary to adjust for the reductions and may result in double-counting
35 of reductions, and removing the reductions may improve transparency of the results and methods. However, EPA

⁷⁸ See <<https://www.epa.gov/natural-gas-star-program>>.

1 will review and potentially incorporate data from Gas STAR’s Methane Challenge program as it becomes available
 2 as part of process for compiling future inventories.

3 **Table 3-45: Gas STAR Reductions (Metric Tons CH₄)**

Source	1990	2005	2011	2012	2013	2014	2015
Production Gas STAR Reductions	-	(35,828)	(44,940)	(45,081)	(30,903)	(30,903)	(30,903)
Production Emissions w/o Gas STAR Reductions	2,300,010	1,924,554	2,015,621	1,947,513	1,861,617	1,795,210	1,656,584
Production Emissions w/ Gas STAR Reductions	2,299,856	1,888,726	1,970,681	1,902,431	1,830,714	1,764,308	1,625,682

4 *Information on Abandoned Wells*

5 Abandoned wells are not currently included in the Inventory. EPA is seeking emission factors and national activity
 6 data available to calculate these emissions. Commenters on previous inventories supported including this source
 7 category, noted that the current data were limited, and suggested reviewing data that will become available in the
 8 future. EPA has identified studies with data on abandoned wells (Townsend-Small et al. 2016 and Kang et al. 2016),
 9 and EPA may provide an information box on this source (without including the estimate in emissions totals) in the
 10 final Inventory and will consider including an estimate for this source in future inventories.

11 **Plans for 2018 GHG Inventory (1990-2016) and Future GHG Inventories**

12 EPA will review data available from the GHGRP, in particular new data on hydraulically fractured oil well
 13 completions and workovers and new well-specific information, available in 2017 for the first time. EPA will
 14 consider revising its method to take into account the new GHGRP data. EPA will continue to review CO₂ data from
 15 GHGRP and make updates consistent with CH₄ updates as appropriate.

16 EPA will review data available from the recent Information Collection Request (ICR) for the oil and natural gas
 17 industry⁷⁹ for potential updates to the Inventory, including improving national-level activity data estimates, and will
 18 assess new data received by the Methane Challenge Program on an ongoing basis, which may be used to confirm or
 19 improve existing estimates and assumptions.

20 EPA continues to track studies that contain data that may be used to update the Inventory.

21 EPA seeks stakeholder feedback on these future plans.

22 **Box 3-7: Carbon Dioxide Transport, Injection, and Geological Storage**

23 Carbon dioxide is produced, captured, transported, and used for Enhanced Oil Recovery (EOR) as well as
 24 commercial and non-EOR industrial applications. This CO₂ is produced from both naturally-occurring CO₂
 25 reservoirs and from industrial sources such as natural gas processing plants and ammonia plants. In the Inventory,
 26 emissions from naturally-produced CO₂ are estimated based on the specific application.

27 In the Inventory, CO₂ that is used in non-EOR industrial and commercial applications (e.g., food processing,
 28 chemical production) is assumed to be emitted to the atmosphere during its industrial use. These emissions are
 29 discussed in the Carbon Dioxide Consumption section. The naturally-occurring CO₂ used in EOR operations is
 30 assumed to be fully sequestered. Additionally, all anthropogenic CO₂ emitted from natural gas processing and
 31 ammonia plants is assumed to be emitted to the atmosphere, regardless of whether the CO₂ is captured or not. These
 32 emissions are currently included in the Natural Gas Systems and the Ammonia Production sections of the Inventory
 33 report, respectively.

34 IPCC includes methodological guidance to estimate emissions from the capture, transport, injection, and geological
 35 storage of CO₂. The methodology is based on the principle that the carbon capture and storage system should be

⁷⁹ <https://www.epa.gov/controlling-air-pollution-oil-and-natural-gas-industry/oil-and-gas-industry-information-requests>

1 handled in a complete and consistent manner across the entire Energy sector. The approach accounts for CO₂
 2 captured at natural and industrial sites as well as emissions from capture, transport, and use. For storage specifically,
 3 a Tier 3 methodology is outlined for estimating and reporting emissions based on site-specific evaluations. However,
 4 IPCC (IPCC 2006) notes that if a national regulatory process exists, emissions information available through that
 5 process may support development of CO₂ emissions estimates for geologic storage.

6 In the United States, facilities that produce CO₂ for various end-use applications (including capture facilities such as
 7 acid gas removal plants and ammonia plants), importers of CO₂, exporters of CO₂, facilities that conduct geologic
 8 sequestration of CO₂, and facilities that inject CO₂ underground (including facilities conducting EOR), are required
 9 to report greenhouse gas data annually to EPA through its GHGRP. Facilities conducting geologic sequestration of
 10 CO₂ are required to develop and implement an EPA-approved site-specific monitoring, reporting and verification
 11 plan, and to report the amount of CO₂ sequestered using a mass balance approach.

12 Available GHGRP data relevant for this inventory estimate consists of national-level annual quantities of CO₂
 13 captured and extracted for EOR applications for 2010 to 2015. For 2015, data from EPA’s GHGRP (Subpart PP)
 14 were unavailable for use in the current Inventory report due data confidentiality reasons. A linear trend extrapolation
 15 was performed based on previous GHGRP reporting years (2010-2014) to estimate 2015 emissions.

16 EPA will continue to evaluate the availability of additional GHGRP data and other opportunities for improving the
 17 emission estimates.

18 These estimates indicate that the amount of CO₂ captured and extracted from industrial and natural sites for EOR
 19 applications in 2015 is 61.0 MMT CO₂ Eq. (60,988 kt) (see Table 3-46 and Table 3-47). Site-specific monitoring
 20 and reporting data for CO₂ injection sites (i.e., EOR operations) were not readily available, therefore, these estimates
 21 assume all CO₂ is emitted.

22 **Table 3-46: Potential Emissions from CO₂ Capture and Extraction for EOR Operations (MMT**
 23 **CO₂ Eq.)**

Stage	1990	2005	2011	2012	2013	2014	2015
Capture Facilities	4.8	6.5	9.9	9.3	12.2	13.1	13.5
Extraction Facilities	20.8	28.3	48.4	48.9	47.0	46.2	47.5
Total	25.6	34.7	58.2	58.1	59.2	59.3	61.0

24 **Table 3-47: Potential Emissions from CO₂ Capture and Extraction for EOR Operations (kt)**

Stage	1990	2005	2011	2012	2013	2014	2015
Capture Facilities	4,832	6,475	9,877	9,267	12,205	13,093	13,483
Extraction Facilities	20,811	28,267	48,370	48,869	46,984	46,225	47,505

26 3.7 Natural Gas Systems (IPCC Source Category

27 1B2b)

28 *EPA is seeking stakeholder feedback on a number of options for updating the emissions estimates in this section.*
 29 *See Recalculations Discussion below for methods used in the development of the public review draft, and EPA’s*
 30 *memos on updates under consideration for other options being considered:*

31 *[https://www.epa.gov/ghgemissions/updates-under-consideration-petroleum-and-natural-gas-systems-1990-2015-](https://www.epa.gov/ghgemissions/updates-under-consideration-petroleum-and-natural-gas-systems-1990-2015-ghg-inventory)*
 32 *ghg-inventory. It is likely that the methods presented here and the calculated emissions totals will change due to*
 33 *revisions between this public review draft of the Inventory and the final Inventory, but impacts on the total emissions*
 34 *estimate are expected to be minor. See the recalculations discussion below for more details. Note that 2014 results*

1 for CO₂ emissions are being used as a preliminary estimate for 2015 while EPA reviews the activity data and
2 estimation methods for consistency with data sources used for methane calculations.

3 The U.S. natural gas system encompasses hundreds of thousands of wells, hundreds of processing facilities, and
4 over a million miles of transmission and distribution pipelines. Overall, natural gas systems emitted 160.0 MMT
5 CO₂ Eq. (6,401 kt) of CH₄ in 2015, a 19 percent decrease compared to 1990 emissions, and a 1 percent decrease
6 compared to 2014 emissions (see Table 3-48, Table 3-49, and Table 3-50) and 42.4 MMT CO₂ Eq. (42,351 kt) of
7 non-combustion CO₂ in 2015, a 12 percent increase compared to 1990 emissions.

8 The 1990 to 2015 trend is not consistent across segments. Overall, the 1990 to 2015 decrease in CH₄ emissions is
9 due primarily to the decrease in emissions from in the transmission/storage and distribution segments. Over the same
10 time period, the production segments saw increased methane emissions of 42 percent. Methane emissions in the
11 processing segment also decreased over the time series, by 10.2 MMT CO₂ Eq., or 48 percent from 1990 levels.
12 Natural gas systems also emitted 42.4 MMT CO₂ Eq. (42,351 kt) of non-combustion CO₂ in 2015, a 12 percent
13 increase compared to 1990 emissions. The 1990 to 2015 increase in CO₂ is due primarily to flaring; the volume of
14 gas flared increased 93 percent from 1990.

15 CH₄ and non-combustion CO₂ emissions from natural gas systems include those resulting from normal operations,
16 routine maintenance, and system upsets. Emissions from normal operations include: natural gas engine and turbine
17 uncombusted exhaust, bleed and discharge emissions from pneumatic controllers, and fugitive emissions from
18 system components. Routine maintenance emissions originate from pipelines, equipment, and wells during repair
19 and maintenance activities. Pressure surge relief systems and accidents can lead to system upset emissions. Below is
20 a characterization of the four major stages of the natural gas system. Each of the stages is described and the different
21 factors affecting CH₄ and non-combustion CO₂ emissions are discussed.

22 *Production (including gathering and boosting).* In the production stage, wells are used to withdraw raw gas from
23 underground formations. Emissions arise from the wells themselves, and well-site gas treatment facilities such as
24 dehydrators and separators. Gathering and boosting emission sources are not reported under a unique segment, but
25 are included within the production sector. The gathering and boosting segment of natural gas systems comprises
26 gathering and boosting stations (with multiple emission sources on site) and gathering pipelines. The gathering and
27 boosting stations receive natural gas from production sites and transfer it, via gathering pipelines, to transmission
28 pipelines or processing facilities (custody transfer points are typically used to segregate sources between each
29 segment). Emissions from production (including gathering and boosting) account for 65 percent of CH₄ emissions
30 and 44 percent of non-combustion CO₂ emissions from natural gas systems in 2015. Emissions from gathering
31 stations, pneumatic controllers, liquids unloading, and offshore platforms account for most of the CH₄ emissions in
32 2015. Flaring emissions account for most of the non-combustion CO₂ emissions. Due to the activity data source for
33 CO₂ from flaring, it is not possible to develop separate estimates for flaring occurring in natural gas production and
34 flaring occurring in oil production. Total CO₂ emissions from flaring for both natural gas and oil were 18.0 MMT
35 CO₂ in 2015 and are included in the Natural Gas Systems estimates. CH₄ emissions from production increased by 42
36 percent from 1990 to 2015, due primarily to increases in emissions from gathering and boosting stations (due to an
37 increase in the number of stations), increases in emissions from pneumatic controllers (due to an increase in the
38 number of controllers, particularly in the number of intermittent bleed controllers), and chemical injection pumps.
39 CO₂ emissions from production increased 88 percent from 1990 to 2015 due primarily to increases in flaring.

40 *Processing.* In this stage, natural gas liquids and various other constituents from the raw gas are removed, resulting
41 in “pipeline quality” gas, which is injected into the transmission system. Fugitive CH₄ emissions from compressors,
42 including compressor seals, are the primary emission source from this stage. Most of the non-combustion CO₂
43 emissions come from acid gas removal (AGR) units, which are designed to remove CO₂ from natural gas.
44 Processing plants account for 7 percent of CH₄ emissions and 56 percent of non-combustion CO₂ emissions from
45 natural gas systems. CH₄ emissions from processing decreased by 48 percent from 1990 to 2015 as emissions from
46 equipment leaks and compressors (leaks and venting) decreased. CO₂ emissions from processing decreased by 15
47 percent from 1990 to 2015, due to a decrease in acid gas removal emissions.

48 *Transmission and Storage.* Natural gas transmission involves high pressure, large diameter pipelines that transport
49 gas long distances from field production and processing areas to distribution systems or large volume customers
50 such as power plants or chemical plants. Compressor station facilities are used to move the gas throughout the U.S.
51 transmission system. Fugitive CH₄ emissions from these compressor stations, and venting from pneumatic
52 controllers account for most of the emissions from this stage. Uncombusted engine exhaust and pipeline venting are
53 also sources of CH₄ emissions from transmission. Natural gas is also injected and stored in underground formations,

1 or liquefied and stored in above ground tanks, during periods of low demand (e.g., summer), and withdrawn,
 2 processed, and distributed during periods of high demand (e.g., winter). In 2015, emissions from the Aliso Canyon
 3 leak event in Southern California contributed 2.0 MMT CO₂ Eq. to transmission and storage emissions, around 6
 4 percent of total emissions for this segment. Compressors and dehydrators are the primary contributors to emissions
 5 from storage. CH₄ emissions from the transmission and storage sector account for approximately 21 percent of
 6 emissions from natural gas systems, while CO₂ emissions from transmission and storage account for less than 1
 7 percent of the non-combustion CO₂ emissions from natural gas systems. CH₄ emissions from this source decreased
 8 by 42 percent from 1990 to 2015 due to reduced compressor station emissions (including emissions from
 9 compressors and fugitives). CO₂ emissions from transmission and storage have decreased by 37 percent from 1990
 10 to 2015, also due to reduced compressor station emissions.

11 *Distribution.* Distribution pipelines take the high-pressure gas from the transmission system at “city gate” stations,
 12 reduce the pressure and distribute the gas through primarily underground mains and service lines to individual end
 13 users. There were 1,274,976 miles of distribution mains in 2015, an increase of over 330,000 miles since 1990
 14 (PHMSA 2016a; PHMSA 2016b). Distribution system emissions, which account for 7 percent of CH₄ emissions
 15 from natural gas systems and less than 1 percent of non-combustion CO₂ emissions, result mainly from fugitive
 16 emissions from pipelines and stations. An increased use of plastic piping, which has lower emissions than other pipe
 17 materials, has reduced both CH₄ and CO₂ emissions from this stage, as have station upgrades at metering and
 18 regulating (M&R) stations. Distribution system CH₄ emissions in 2015 were 75 percent lower than 1990 levels
 19 (changed from 43.5 MMT CO₂ Eq. to 11.0 MMT CO₂ Eq.), while distribution CO₂ emissions in 2015 were 72
 20 percent lower than 1990 levels (CO₂ emission from this segment are less than 0.1 MMT CO₂ Eq. across the time
 21 series).

22 Total CH₄ emissions for the four major stages of natural gas systems are shown in MMT CO₂ Eq. (Table 3-48) and
 23 kt (Table 3-49). Table 3-50 provides additional information on how the estimates in Table 3-46 were calculated.
 24 Table 3-50 shows the calculated potential CH₄ release (i.e., potential emissions before any controls are applied) from
 25 each stage, and the amount of CH₄ that is estimated to have been flared, captured, or otherwise controlled, and
 26 therefore not emitted to the atmosphere. Subtracting the value for CH₄ that is controlled, from the value for
 27 calculated potential release of CH₄, results in the total net emissions values. More disaggregated information on
 28 potential emissions and emissions is available in Annex 3.6. See Methodology for Estimating CH₄ and CO₂
 29 Emissions from Natural Gas Systems.

30 **Table 3-48: CH₄ Emissions from Natural Gas Systems (MMT CO₂ Eq.)^a**

Stage	1990	2005	2011	2012	2013	2014	2015
Field Production	73.1	97.1	103.6	106.0	105.0	106.5	104.2

Note: Totals may not sum due to independent rounding.

4 **Methodology**

5 The methodology for natural gas emissions estimates presented in this public review draft of the Inventory involves
6 the calculation of CH₄ and CO₂ emissions for over 100 emissions sources, and then the summation of emissions for
7 each natural gas segment.

8 The approach for calculating emissions for natural gas systems generally involves the application of emission factors
9 to activity data. For many sources, the approach uses technology-specific emission factors or emission factors that
10 vary over time and take into account changes to technologies and practices, which are used to calculate net
11 emissions directly. For others, the approach uses what are considered “potential methane factors” and reduction data
12 to calculate net emissions.

1 *Emission Factors.* A primary basis for estimates of CH₄ and non-combustion-related CO₂ emissions from the U.S.
2 natural gas industry is a detailed study by the Gas Research Institute (GRI) and EPA (EPA/GRI 1996). The
3 EPA/GRI study developed over 80 CH₄ emission factors to characterize emissions from the various components
4 within the operating stages of the U.S. natural gas system. The EPA/GRI study was based on a combination of
5 process engineering studies, collection of activity data, and measurements at representative gas facilities conducted
6 in the early 1990s. Methane compositions from the Gas Technology Institute (GTI, formerly GRI) Unconventional
7 Natural Gas and Gas Composition Databases (GTI 2001) are adjusted year to year using gross production for oil and
8 gas supply National Energy Modeling System (NEMS) regions from the EIA. Therefore, emission factors may vary
9 from year to year due to slight changes in the CH₄ composition for each NEMS oil and gas supply module region.
10 The emission factors used to estimate CH₄ were also used to calculate non-combustion CO₂ emissions. Data from
11 GTI 2001 were used to adapt the CH₄ emission factors into non-combustion related CO₂ emission factors.
12 Additional information about CO₂ content in transmission quality natural gas was obtained from numerous U.S.
13 transmission companies to help further develop the non-combustion CO₂ emission factors.

14 Another key source of emission factors is the Greenhouse Gas Reporting Program (GHGRP) Subpart W data (EPA
15 2016). In the production segment, GHGRP data were used to develop emission factors for gas well completions and
16 workovers (refracturing) with hydraulic fracturing, pneumatic controllers and chemical injection pumps, condensate
17 tanks, and liquids unloading. In the processing segment, GHGRP data were used to develop emission factors for
18 fugitives, compressors, flares, dehydrators, and blowdowns/venting. In the transmission and storage segment,
19 GHGRP data were used to develop factors for pneumatic controllers.

20 Other data sources used for emission factors include Marchese et al. for gathering stations, Zimmerle et al. for
21 transmission and storage station fugitives and compressors, and Lamb et al. for pipelines.

22 See Annex 3.6 for more detailed information on the methodology and data used to calculate CH₄ and non-
23 combustion CO₂ emissions from natural gas systems.

24 *Activity Data.* Activity data were taken from the following sources: DrillingInfo, Inc (DrillingInfo 2016); American
25 Gas Association (AGA 1991 through 1998); Bureau of Ocean Energy Management, Regulation and Enforcement
26 (previous Minerals and Management Service) (BOEMRE 2011a, 2011b, 2011c, 2011d); Natural Gas Liquids
27 Reserves Report (EIA 2005); Natural Gas Monthly (EIA 2016a, 2016b, 2016c); the Natural Gas STAR Program
28 annual emissions savings (EPA 2013c); Oil and Gas Journal (OGJ 1997 through 2015); Pipeline and Hazardous
29 Materials Safety Administration (PHMSA 2016a, 2016b); Federal Energy Regulatory Commission (FERC 2015);
30 Greenhouse Gas Reporting Program (EPA 2016); other Energy Information Administration data and publications
31 (EIA 2001, 2004, 2012, 2014); (EPA 1999); Conservation Commission (Wyoming 2015); and the Alabama State
32 Oil and Gas Board (Alabama 2015).

33 For a few sources, recent direct activity data are not available. For these sources, either 2014 data was used as a
34 proxy for 2015 data, or a set of industry activity data drivers was developed and used to calculate activity data over
35 the time series. Drivers include statistics on gas production, number of wells, system throughput, miles of various
36 kinds of pipe, and other statistics that characterize the changes in the U.S. natural gas system infrastructure and
37 operations. More information on activity data and drivers is available in Annex 3.6.

38 *Calculating Net Emissions.* For most sources, emissions are calculated directly by applying emission factors to
39 activity data. However, for certain sectors, some sources are calculated using potential emission factors, and the
40 step of deducting CH₄ that is not emitted from the total CH₄ potential estimates to develop net CH₄ emissions is
41 applied. To take into account use of such technologies, data, where available, are collected on both regulatory and
42 voluntary reductions. Regulatory actions addressed using this method include National Emission Standards for
43 Hazardous Air Pollutants (NESHAP) regulations for dehydrator vents. Voluntary reductions included in the GHG
44 Inventory are those reported to Natural Gas STAR.

45 In this public review draft of the Inventory, EPA included an emissions estimate from the Aliso Canyon leak
46 event.⁸⁰ EPA used the estimate of the leak published by the California Air Resources Board (99,650 MT for the

⁸⁰ For more information on the Aliso Canyon event, and the measurements conducted of the leak, please see Ensuring Safe and Reliable Underground Natural Gas Storage, Final Report of the Interagency Task Force on Natural Gas Storage Safety, available

1 duration of the leak), adjusted to only include those emissions that occurred in 2015 (2016 emissions will be
2 included in next Inventory). The 2015 emissions estimate of 78,350 MT CH₄ was added to the 2015 estimate of
3 fugitive emissions from storage wells, calculated with an emission factor approach, resulting in total emissions from
4 storage wells in 2015 of 92,590 MT CH₄. For more information, please see *Inventory of U.S. Greenhouse Gas*
5 *Emissions and Sinks 1990-2015: Update under Consideration for Storage Segment Emissions*.⁸¹ EPA continues to
6 seek stakeholder feedback on this update and on the memo.

7 **Uncertainty and Time-Series Consistency**

8 EPA's planned uncertainty analysis is discussed in the Planned Improvements section.

9 New data available starting in 2011 have improved estimates of emissions from Natural Gas Systems. Many of the
10 previously available data sets were collected in the 1990s. To develop a consistent time series for 1990-2015, for
11 sources with new data, EPA reviewed available information on factors that may have resulted in changes over the
12 time series (e.g. regulations, voluntary actions) and requested stakeholder feedback on trends as well. For most
13 sources, EPA developed annual data for 1993-2010 by interpolating activity data or emission factors or both
14 between 1992 and 2011 data points.

15 Information on time-series consistency for sources updated in this public review draft can be found in the
16 Recalculation Discussion below, with additional detail provided in the 2017 Production and Processing memos. For
17 information on other sources, please see the Methodology Discussion above.

18 **QA/QC and Verification Discussion**

19 The natural gas emission estimates in the Inventory are continually being reviewed and assessed to determine
20 whether emission factors and activity factors accurately reflect current industry practices. A QA/QC analysis was
21 performed for data gathering and input, documentation, and calculation. QA/QC checks are consistently conducted
22 to minimize human error in the model calculations. EPA performs a thorough review of information associated with
23 new studies, GHGRP data, regulations, public webcasts, and the Natural Gas STAR Program to assess whether the
24 assumptions in the Inventory are consistent with current industry practices. The EPA has a multi-step data
25 verification process for GHGRP data, including automatic checks during data-entry, statistical analyses on
26 completed reports, and staff review of the reported data. Based on the results of the verification process, the EPA
27 follows up with facilities to resolve mistakes that may have occurred.

28 As in previous years, EPA conducted early engagement and communication with stakeholders on updates prior to
29 public review. In December 2016 and January 2017, EPA stakeholder webinars on GHG data for oil and gas. In
30 early 2017, EPA released memos detailing updates under consideration and requesting stakeholder feedback. EPA
31 discusses preliminary stakeholder feedback received in the public review draft. EPA continues to receive and review
32 feedback on the options presented, and may revise the recalculations in the final 2017 GHG Inventory based on that
33 feedback.

34 In recent years, several studies have measured emissions at the source level and at the national or regional level and
35 calculated emissions estimates that may differ from the GHG Inventory. There are a variety of potential uses of data
36 from new studies, including replacing a previous estimate or factor, verifying or QA of an existing estimate or
37 factor, and identifying areas for updates.

38 In general, there are two major types of studies related to oil and gas greenhouse gas data: studies that focus on
39 measurement or quantification of emissions from specific activities, processes and equipment, and studies that focus
40 on verification of estimates through inverse modeling. The first type of study can lead to direct improvements to or
41 verification of GHG Inventory estimates. In the past few years, EPA has reviewed and in many cases, incorporated

at <<http://www.energy.gov/sites/prod/files/2016/10/f33/Ensuring%20Safe%20and%20Reliable%20Underground%20Natural%20Gas%20Storage%20-%20Final%20Report.pdf>>.

⁸¹ <https://www.epa.gov/sites/production/files/2017-01/documents/memo_on_aliso_canyon_estimate_for_u.s._ghgi_1.10.17.pdf>.

1 data from these data sources. The second type of study can provide general indications on potential over- and
2 under-estimates. A key challenge in using these types of studies to assess GHG Inventory results is having a relevant
3 basis for comparison. In an effort to improve the ability to compare the national-level GHG inventory with
4 measurement results that may be at other scales, a team at Harvard University along with EPA and other coauthors
5 developed a gridded inventory of U.S. anthropogenic methane emissions with 0.1° x 0.1° spatial resolution, monthly
6 temporal resolution, and detailed scale-dependent error characterization.⁸² The inventory is designed to be
7 consistent with the 2016 *Inventory of U.S. Greenhouse Gas Emissions and Sinks* (1990-2014) estimates for the
8 year 2012, which presents national totals for different source types.⁸³

9 Recalculations Discussion

10 The EPA received information and data related to the emission estimates through the Inventory preparation process,
11 previous Inventories' formal public notice periods, GHGRP data, and new studies. The EPA carefully evaluated
12 relevant information available, and made several updates in this public review draft of the Inventory, including
13 revisions to production segment activity and emissions data, gathering and boosting facility emissions, and
14 processing segment activity and emissions data. Additional information on inclusion of the Aliso Canyon emissions
15 can be found in the Methodology section above and in the 2017 Transmission and Storage Memo⁸⁴ and not in the
16 Recalculation Discussion section as it did not involve recalculation of a previous year of the Inventory.

17 In January 2017, the EPA released draft memoranda that discussed the changes under consideration and requested
18 stakeholder feedback on those changes.⁸⁵ In this public review draft of the 2017 GHG Inventory (1990-2015), EPA
19 has selected from the options presented in the 2017 Production and Processing memos to develop emissions
20 estimates. EPA continues to receive and review feedback on the options presented, and it is likely that the methods
21 presented here and the calculated emissions totals will change due to revisions between this public review draft of
22 the 1990-2015 Inventory and the final Inventory, but impacts on the total emissions estimate are expected to be
23 minor. The impact of all revisions to natural gas systems is a decrease of 15.3 MMT CO₂ Eq., or 9 percent,
24 comparing the 2014 value from the previous Inventory to this public review draft Inventory. Over the time series,
25 the average change is a decrease of 15 MMT CO₂ Eq., or 8 percent.

26 Recalculations for the production segment (including gathering and boosting facilities) resulted in a small decrease
27 in the 2014 CH₄ emission estimate, from 109.0 MMT CO₂ Eq. in the previous Inventory, to 106.5 MMT CO₂ Eq. in
28 this public review draft of the Inventory, or 2 percent. Over the time series, the average change is an increase of 9.5
29 MMT CO₂ Eq., or 10 percent.

30 Recalculations for the processing segment resulted in a decrease of 12.8 MMT CO₂ Eq., or 54 percent comparing the
31 2014 value from the previous Inventory to this public review draft Inventory. Over the time series, the average
32 change was 28 percent.

33 Although there were no methodological updates to the transmission and storage segment, recalculations due to
34 updated data (e.g., GHGRP station counts, the GHGRP split between dry and wet seal centrifugal compressors, and
35 GHGRP pneumatic controller data) impacted emissions estimates, resulting in an average increase in calculated
36 emissions over the time series from this segment of around 24 metric tons CH₄, or less than 0.01 percent.

37 Although there were no methodological updates to the distribution segment, recalculations due to updated data (e.g.,
38 GHGRP M&R station counts) impacted emissions estimates, resulting in an average increase in calculated emissions
39 over the time series from this segment of around 664 metric tons CH₄, or 0.1 percent.

1 Production

2 This section references the Inventory production segment supporting memoranda: “Revisions to Natural Gas and
3 Petroleum Production Emissions,” (the “2017 Production Memo”).⁸⁶ This memorandum contains further details and
4 documentation of recalculations.

5 Tanks

6 In the public review draft, EPA developed emissions estimates for condensate tanks using GHGRP data and an
7 equipment-based approach. For more information, please see pages 5 through 14 of the 2017 Production Memo.
8 Using 2015 GHGRP data, EPA developed a value for large tanks per well (0.09) and small tanks per well (0.32), a
9 fraction of tanks in each of five categories (large tanks with flares, large tanks with VRU, uncontrolled large tanks,
10 small tanks with flares, and small tanks without flares) for 2015, and corresponding emission factors. The count of
11 large and small tanks per well of 0.09 and 0.32, respectively, was applied to total gas well counts for each year of
12 the time series. The 2015 fraction of tanks in each control category was applied to tanks for the years 2011 to 2015.
13 For 1990, it was assumed that 50 percent of large tanks were controlled with a flare and 50 percent were
14 uncontrolled, and all small tanks were in the uncontrolled category. EPA then linearly interpolated from 1990 to
15 2011 for each category. Category-specific emission factors developed from 2015 GHGRP data were applied for
16 each year of the time series. EPA also developed a per-tank emission factor for malfunctioning dump valves. In the
17 GHGRP, only large tanks report malfunctioning dump valves. EPA has applied the emission factor to all large tanks
18 for each year of the time series. As the new method results in the direct calculation of net emissions, EPA removed
19 the tank reductions line item (an estimate of reductions from NESHAP). This revision on average resulted in a 74
20 percent decrease in the estimated emission for tanks across the time series. EPA received initial stakeholder
21 feedback on the updates under consideration for this source supporting the revision, but also received feedback
22 suggesting that the GHGRP methods for tanks could result in potential underestimates in reported emissions. EPA
23 received feedback from two commenters supporting the throughput-based approach over the tank count based
24 approach (the approach used here), noting that throughput more directly relates to tank emissions than the number of
25 tanks. Based on this initial feedback, EPA is considering using the throughput-based approach for the final 2017
26 GHG inventory. The throughput-based approach would result in lower national methane emissions than the tank-
27 based approach, with 2014 oil tank emissions around 30 percent lower than emissions calculated using the tank-
28 based approach presented here. As noted above, EPA continues to receive and review feedback on the options
29 presented and will also assess information received as public review comments.

30 **Table 3-53: National Tank Activity Data (Number of Tanks) by Category and National**
31 **Emissions (Metric Tons CH₄)**

Activity Data/Emissions	1990	2005	2011	2012	2013	2014	2015

⁸⁶ See <<https://www3.epa.gov/climatechange/ghgemissions/usinventoryreport/natural-gas-systems.html>>.

1 *Well Counts*

2 EPA has used a more recent version of the DrillingInfo data set to update well counts data in this public review draft
 3 of the Inventory. For more information, see pages 19 through 20 of the 2017 Production Memo. This update
 4 resulted in a decrease of 1 percent in gas well counts on average over the time series. EPA received feedback that
 5 stakeholders generally support the revision as introducing more consistency with recently published well count
 6 estimates. EPA continues to compare current estimates with stakeholder well counts also derived from DrillingInfo,
 7 investigate differences, and may further revise the well count estimates in the final Inventory.

8 **Table 3-54: Gas Well Count Data**

Gas Well Count	1990	2005	2011	2012	2013	2014	2015
Number of Gas Wells	214,220	371,385	459,948	457,984	450,997	452,870	440,496
<i>Previous Estimated Number of Gas Wells</i>	<i>218,709</i>	<i>373,903</i>	<i>463,198</i>	<i>460,588</i>	<i>454,491</i>	<i>456,140</i>	<i>NA</i>
Percent Change	-2%	-1%	-1%	-1%	-1%	-1%	NA

NA – Not Applicable

9 *Equipment Counts (Fugitive Sources)*

10 Additional reporting to GHGRP for RY2015 improved EPA’s allocation of GHGRP equipment counts between
 11 natural gas and petroleum for certain equipment leak category sources. EPA used the RY2015 reporting data to
 12 develop improved counts of equipment per well. For more information, please see pages 20 to 22 of the 2017
 13 Production Memo. For the public review draft, EPA developed per well counts using 2015 GHGRP and applied
 14 those to national gas well counts for years 2011 through 2015. The per well counts for 1990 through 1992 were
 15 retained from previous inventories, and counts for 1993 through 2010 were developed by linear interpolation.
 16 Overall, the change decreased calculated emissions over the time series by around 11 percent, with the largest
 17 decreases in meters/piping (20 percent), dehydrators (13 percent), and compressors (16 percent). Initial stakeholder
 18 feedback supported this update.

19 **Table 3-55: National Equipment Counts for Fugitive Sources and National Emissions (Metric
 20 Tons CH₄)**

Activity Data/Emissions	1990	2005	2011	2012	2013	2014	2015

NA – Not Applicable

21 *Pneumatic Controllers and Chemical Injection Pumps*

22 Total per well counts of pneumatic controllers and chemical injection pump were updated using year 2015 GHGRP
 23 data. The 2015 GHGRP data set allowed for improved estimates of the counts of gas wells in GHGRP, which
 24 improved the activity factors of counts of controllers and pumps per gas well. These per well counts were applied to
 25 years 2011 through 2015. For years 2011 through 2015, GHGRP year-specific data on fractions of pneumatic
 26 controllers in each category (high bleed “HB”, low bleed “LB”, and intermittent “IB”) were applied to the counts of
 27 pneumatic controllers. The 1990 through 1992 per well counts of controllers in each category and pumps were
 28 retained for 1990 through 1992 and then the per well counts of pneumatic controllers in each category and pumps
 29 for 1993 through 2010 were developed by linear interpolating from 1992 through 2011. Category-specific emissions
 30 factors developed from year 2014 GHGRP data were applied throughout the time series. The recalculations using
 31 the latest GHGRP data resulted in only minor changes in the annual fractions of controllers in each category, and
 32 only minor changes in total calculated emissions.

1 **Table 3-56: Pneumatic Controller and Chemical Injection Pump National Equipment Counts**

3 *Liquids Unloading*

4 For the public review draft, EPA updated its estimates for liquids unloading to use data from GHGRP. For more
 5 information, please see pages 23 to 25 of the 2017 Production Memo.

6 To develop this estimate, EPA retained the assumption that 56 percent of all gas wells conduct liquids unloading
 7 (total percent of wells that vent for liquids unloading and wells that do not vent for liquids unloading (i.e., use of
 8 non-emitting systems)) over the time series (developed from API/ANGA report). EPA also retained the assumption
 9 that in 1990, all of the 56 percent of wells with liquids unloading issues vent without plunger lifts. For the years
 10 2011 to 2015, EPA applied the 2015 GHGRP fraction of gas wells that vent for liquids unloading (16.8 percent), and
 11 applied year-specific fractions of wells venting with plunger lifts and wells venting without plunger lifts. For years
 12 1991 to 2010, EPA interpolated from the percentages of wells in each category for 1990 to 2011. For all years of the
 13 time series, EPA applied average EFs calculated from 2011 to 2015 GHGRP data. The activity data assumptions and
 14 emission factors were developed and applied at the national level, whereas, the previous year's Inventory calculated
 15 emissions with regional factors.

16 The recalculation for liquids unloading emissions resulted in an average decrease of 329,102 MT or 45 percent over
 17 the time series. The decrease in calculated emissions is much smaller in recent years (e.g., 12 percent for 2010
 18 through 2014), than earlier years of the time series (e.g., 54 percent for 1990 through 1995). Initial stakeholder
 19 feedback supported the use of liquids unloading data from GHGRP, but suggested developing regional activity
 20 factors.

21 **Table 3-57: National Liquids Unloading Activity Data by Category and National Emissions**
 22 **(Metric Tons CH₄)**

Activity Data/Emissions	1990	2005	2011	2012	2013	2014	2015
Wells Venting w/o Plunger Lifts (Counts)	120,499	76,775	29,627	32,687	35,778	35,114	29,896

1 *Gathering and Boosting Episodic Emissions*

2 For the public review draft, EPA applied a factor developed in the Marchese study (37 metric tons CH₄ per station)
3 to calculate emissions from gathering and boosting station episodic events. For more information, please see pages
4 25 to 26 of the 2017 Production Memo. This value was applied to all stations for each year of the time series. A
5 stakeholder comment received on this update expressed support for delaying this update and instead using data
6 reported to GHGRP as a basis for including an estimate in the next Inventory.

9 **Processing**

10 This section references the memo *Inventory of U.S. Greenhouse Gas Emissions and Sinks 1990-2015: Updates*
11 *under Consideration for Natural Gas Systems Processing Segment Emissions (2017 Processing Memo)*.⁸⁷

12 In this public review draft of the Inventory, EPA has selected from the options presented in the 2017 Processing
13 Memo to develop emissions estimates. EPA has received initial feedback (one comment) on the 2017 Processing
14 Memo suggesting that the GHGRP-based approaches would underestimate emissions and recommending use of the
15 Marchese et al. data set, using either site-level estimates or allocating Marchese site-level estimates to specific
16 sources using GHGRP emissions data. EPA continues to receive and review feedback on the options presented and
17 may make revisions to these estimates based on that feedback and feedback received on this public review draft.

18 The combined impact of revisions to 2014 processing segment emissions, compared to the previous Inventory, is a
19 decrease in CH₄ emissions from 24.0 to 11.1 MMT CO₂ Eq. (12.8 MMT CO₂ Eq., or 54 percent).

20 The recalculations resulted in an average decrease in emission estimates across the 1990 to 2014 time series,
21 compared to the previous Inventory, of 5.7 MMT CO₂ Eq., or 28 percent.

22 This section describes the approach that was used to calculate emissions in this public review draft. EPA will
23 continue to assess stakeholder feedback to develop updated estimates for the final Inventory.

24 *Station Fugitives, Compressors, Flares and Dehydrators*

25 GHGRP data were used to update the estimates for station fugitives, compressors, flares, and dehydrators. For more

⁸⁷ See < https://www.epa.gov/sites/production/files/2017-01/documents/2017_ghgi_ng_revision_under_consideration_-_gas_proc_1.17.pdf>.

1 information, see pages 5 to 10, and 12 to 16 of the 2017 Processing Memo. Linear interpolation was used to create
 2 time series consistency between earlier years' emission factors and activity factors (1990 through 1992) that
 3 generally rely on data from GRI/EPA 1996 and the GHGRP emission and activity factors for recent years. However,
 4 the plant fugitive emission factors in previous Inventories included plant fugitives but not compressor fugitives, and
 5 separate emission factors were applied for compressor emissions (including compressor fugitive and vented
 6 sources). There is also some overlap between those categories and the flare and dehydrator categories. Because of
 7 these differences, the two sets of emission factors (GRI/EPA and factors calculated from GHGRP) cannot be
 8 directly compared. For the purpose of interpolating for the time series, in this public review draft of the Inventory,
 9 the EPA calculated plant-level emission factors for processing stations that include plant and compressor fugitive
 10 sources, compressor vented sources, flares, and dehydrators. The previous Inventory emission factors were used for
 11 1990 through 1992; emission factors from GHGRP were used for 2011 through 2015. Emission factors for 1993
 12 through 2010 were developed through linear interpolation.

13 In this public review draft of the Inventory, the EPA incorporated GHGRP average values of reciprocating and
 14 centrifugal compressors per processing plant, using year 2015 data. These values were applied for 2011 through
 15 2015. GHGRP data for 2011 through 2015 are used to develop year-specific splits between centrifugal compressor
 16 seal types (wet versus dry seals). GHGRP year 2015 data were used to develop emission factors on a per-plant basis
 17 for fugitives, flares, and dehydrators, and a per-compressor basis for compressors. Emission factors for dry seal
 18 centrifugal compressors were developed using GHGRP data supplemented with the previous Inventory emission
 19 factor for dry seal emissions.

20 In order to create time series consistency between earlier years' per plant compressor count estimates (1990 to 1992)
 21 and the most recent years' per plant compressor count estimates (2011 to 2015) that were calculated using GHGRP
 22 data, compressor counts for the years 1993 through 2010 were calculated using linear interpolation between the data
 23 endpoints of 1992 and 2011.

24 The overall impact of using revised emissions data and activity data from GHGRP is a decrease in emissions for
 25 fugitives and compressors. For the year 2014, the calculated CH₄ emissions decrease due to use of revised emission
 26 factors and activity data for processing plant fugitives, compressor venting, flares, and dehydrators is approximately
 27 17.2 MMT CO₂ Eq.

28 *Gas Engines and Turbines*

29 In the public review draft, the estimates for gas engines and gas turbines were updated to incorporate data from
 30 GHGRP. For more information, please see pages 10 to 11 of the 2017 Processing Memo. GHGRP data were used to
 31 develop an updated value for million horsepower-hours (MMHP_{hr}) per plant for both gas engines and gas turbines.
 32 These values were applied to plant counts for years 2011 to 2015. The previous estimates of MMHP_{hr} per plant
 33 were retained for 1990 through 1992, and values for 1993 to 2010 were developed by linear interpolation between
 34 the 1992 and 2011 values. EPA retained the previous Inventory emission factor and applied it for all years of the
 35 time series. The recalculation for gas engines resulted in an average increase in the estimate of 24,496 MT, or 16
 36 percent over the time series. The recalculation for gas turbines resulted in an average decrease in the estimate of 395
 37 MT, or 8 percent over the time series.

38 *Blowdown Venting*

39 In the public review draft, the estimate for blowdown venting was updated to incorporate data from GHGRP. For
 40 more information, please see pages 11 to 12 of the 2017 Processing Memo. A per-plant emission factor was
 41 developed from 2015 GHGRP data, and applied to plant counts for years 2011 through 2015. The previous emission
 42 factors were retained for 1990 through 1992, and values for 1993 through 2010 were developed by linear
 43 interpolation between the 1992 and 2011 values. The recalculation resulted in an average decrease in the estimate of
 44 7,769 MT or 17 percent over the time series.

NA – Not Applicable

4 **Gas STAR Reductions in the Processing Segment**

5 The EPA's approach for revising the Inventory methodology to incorporate GHGRP data in the processing segment
6 resulted in net emissions being directly calculated for all sources in each year of the time series. This obviated the
7 need to apply Gas STAR reductions data for these sources. EPA has removed the Gas STAR reductions for the

1 processing segment. Over the 1990 to 2015 time series, annual Gas STAR reductions averaged 76,828 MT CH₄, or
 2 1.9 MMTCO₂ Eq.

3 **Planned Improvements**

4 **Plans for Final Inventory**

5 EPA continues to receive and review stakeholder feedback on the 2017 Production Memo, the 2017 Processing
 6 Memo, and the 2017 storage revisions to incorporate Aliso Canyon emissions. EPA will consider this feedback,
 7 along with feedback on this public review draft as it develops the final Inventory.

8 EPA seeks feedback on the methods applied in this public review draft, on other options presented in the memos,
 9 and on additional planned improvements under consideration discussed in this section.

10 *Uncertainty*

11 The most recent uncertainty analysis for the natural gas systems emission estimates in the Inventory was conducted
 12 for the 1990 to 2009 Inventory that was released in 2011. Since the analysis was last conducted, several of the
 13 methods used in the Inventory have changed, and industry practices and equipment have evolved. In addition, new
 14 studies and other data sources such as those discussed in the sections below offer improvement to understanding and
 15 quantifying the uncertainty of some emission source estimates. EPA is planning for the final Inventory an update to
 16 the uncertainty analysis conducted for the Inventory published in 2011 to reflect the new information. It is difficult
 17 to project whether updated uncertainty bounds around CH₄ emission estimates would be wider, tighter, or about the
 18 same as the current uncertainty bounds that were developed for the Inventory published in 2011 (i.e., minus 19
 19 percent and plus 30 percent).

20 *Gas STAR Reductions in the Production Segment*

21 The Inventory estimate for the Production Segment takes into account reductions reported to the Natural Gas STAR
 22 program.⁸⁸ EPA is considering removing the Gas STAR reductions from its calculations for the production segment.
 23 In this public review draft of the Inventory, Gas STAR production segment reductions reduce calculated potential
 24 emissions by an average of 5 percent over the times series. Many emissions sources in the Inventory are now
 25 calculated using net emissions approaches, with technology-specific activity data and emission factors, and annual
 26 data from the GHGRP. It may not be necessary to adjust for the reductions and may result in double-counting of
 27 reductions, and removing the reductions may improve transparency of the results and methods. However, EPA will
 28 review and potentially incorporate data from Gas STAR’s Methane Challenge program as it becomes available as part
 29 of process for compiling future inventories.

30 **Table 3-61: Gas STAR Reductions (Metric Tons CH₄)**

Source	1990	2005	2011	2012	2013	2014	2015
Production Gas STAR Reductions	-	(263,654)	(448,833)	(440,790)	(463,903)	(494,184)	(530,058)
Production Emissions w/o Gas STAR Reductions	2,925,162	4,149,308	4,590,938	4,678,607	4,665,013	4,752,783	4,696,873
Production Emissions w/ Gas STAR Reductions	2,925,162	3,885,654	4,142,104	4,237,817	4,201,110	4,258,599	4,166,815

31 If implemented, this change would increase the production segment estimate by an average of 5 percent over the
 32 time series. There are more Gas STAR reductions in later years of the time series due to an assumption that ongoing
 33 activities are added at the same rate in years with incomplete data. As such this change would impact the trend. For

⁸⁸ See <<https://www.epa.gov/natural-gas-star-program>>.

example, in this public review draft, emissions from production decrease by 7 percent from 2005 to 2015; removing the Gas STAR reductions would change this decrease to 15 percent. The change from 2014 to 2015, a decrease of 2 percent in the public review draft, would change to a decrease of 1 percent in the final Inventory, if this change is implemented.

Information on Abandoned Wells

Abandoned wells are not currently included in the Inventory. EPA is seeking emission factors and national activity data available to calculate these emissions. Commenters on previous inventories supported including this source category, noted that the current data were limited, and suggested reviewing data that will become available in the future. EPA has identified studies with data on abandoned wells (Townsend-Small et al. 2016 and Kang et al. 2016), and EPA may provide an information box on this source (without including the estimate in emissions totals) in the final Inventory and will consider including an estimate for this source in future inventories.

Plans for 1990-2016 and Future Inventories

EPA seeks stakeholder feedback on these future plans.

EPA will review data available from GHGRP, in particular new data on gathering and boosting stations, gathering pipelines, and transmission pipeline blowdowns and new well-specific information, available in 2017 for the first time. EPA will consider revising its method to take into account the new GHGRP data. EPA will continue to review CO₂ data from GHGRP and make updates consistent with CH₄ updates as appropriate.

EPA will review data available from the recent Information Collection Request (ICR) for the oil and natural gas industry⁸⁹ for potential updates to the Inventory, including improving national-level activity data estimates, and will assess new data received by the Methane Challenge Program on an ongoing basis, which may be used to confirm or improve existing estimates and assumptions.

EPA continues to track studies that contain data that may be used to update the Inventory.

Key studies in progress include DOE-funded work on the following sources: vintage and new plastic pipelines (distribution segment), industrial meters (distribution segment), and sources within the gathering and storage segments.⁹⁰

3.8 Energy Sources of Indirect Greenhouse Gas Emissions

In addition to the main greenhouse gases addressed above, many energy-related activities generate emissions of indirect greenhouse gases. Total emissions of nitrogen oxides (NO_x), carbon monoxide (CO), and non-CH₄ volatile organic compounds (NMVOCs) from energy-related activities from 1990 to 2015 are reported in Table 3-62.

Table 3-62: NO_x, CO, and NMVOC Emissions from Energy-Related Activities (kt)

Gas/Activity	1990	2005	2011	2012	2013	2014	2015

^a These values are presented for informational purposes only and are not included in totals.

Note: Totals may not sum due to independent rounding.

1 Methodology

2 Emission estimates for 1990 through 2015 were obtained from data published on the National Emission Inventory
3 (NEI) Air Pollutant Emission Trends web site (EPA 2016), and disaggregated based on EPA (2003). Emission
4 estimates for 2012 and 2013 for non-electric generating units (EGU) and non-mobile sources are held constant from
5 2011 in EPA (2016). Emissions were calculated either for individual categories or for many categories combined,
6 using basic activity data (e.g., the amount of raw material processed) as an indicator of emissions. National activity
7 data were collected for individual applications from various agencies.

8 Activity data were used in conjunction with emission factors, which together relate the quantity of emissions to the
9 activity. Emission factors are generally available from the EPA's *Compilation of Air Pollutant Emission Factors*,
10 *AP-42* (EPA 1997). The EPA currently derives the overall emission control efficiency of a source category from a
11 variety of information sources, including published reports, the 1985 National Acid Precipitation and Assessment
12 Program emissions inventory, and other EPA databases.

13 Uncertainty and Time-Series Consistency

14 Uncertainties in these estimates are partly due to the accuracy of the emission factors used and accurate estimates of
15 activity data. A quantitative uncertainty analysis was not performed.

16 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
17 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
18 above.

19 3.9 International Bunker Fuels (IPCC Source 20 Category 1: Memo Items)

21 Emissions resulting from the combustion of fuels used for international transport activities, termed international
22 bunker fuels under the UNFCCC, are not included in national emission totals, but are reported separately based upon
23 location of fuel sales. The decision to report emissions from international bunker fuels separately, instead of
24 allocating them to a particular country, was made by the Intergovernmental Negotiating Committee in establishing

1 the Framework Convention on Climate Change.⁹¹ These decisions are reflected in the IPCC methodological
 2 guidance, including IPCC (2006), in which countries are requested to report emissions from ships or aircraft that
 3 depart from their ports with fuel purchased within national boundaries and are engaged in international transport
 4 separately from national totals (IPCC 2006).⁹²

5 Two transport modes are addressed under the IPCC definition of international bunker fuels: aviation and marine.⁹³
 6 Greenhouse gases emitted from the combustion of international bunker fuels, like other fossil fuels, include CO₂,
 7 CH₄ and N₂O for marine transport modes, and CO₂ and N₂O for aviation transport modes. Emissions from ground
 8 transport activities—by road vehicles and trains—even when crossing international borders are allocated to the
 9 country where the fuel was loaded into the vehicle and, therefore, are not counted as bunker fuel emissions.

10 The *2006 IPCC Guidelines* distinguish between different modes of air traffic. Civil aviation comprises aircraft used
 11 for the commercial transport of passengers and freight, military aviation comprises aircraft under the control of
 12 national armed forces, and general aviation applies to recreational and small corporate aircraft. The *2006 IPCC*
 13 *Guidelines* further define international bunker fuel use from civil aviation as the fuel combusted for civil (e.g.,
 14 commercial) aviation purposes by aircraft arriving or departing on international flight segments. However, as
 15 mentioned above, and in keeping with the *2006 IPCC Guidelines*, only the fuel purchased in the United States and
 16 used by aircraft taking-off (i.e., departing) from the United States are reported here. The standard fuel used for civil
 17 aviation is kerosene-type jet fuel, while the typical fuel used for general aviation is aviation gasoline.⁹⁴

18 Emissions of CO₂ from aircraft are essentially a function of fuel use. Nitrous oxide emissions also depend upon
 19 engine characteristics, flight conditions, and flight phase (i.e., take-off, climb, cruise, decent, and landing). Recent
 20 data suggest that little or no CH₄ is emitted by modern engines (Anderson et al. 2011), and as a result, CH₄
 21 emissions from this category are considered zero. In jet engines, N₂O is primarily produced by the oxidation of
 22 atmospheric nitrogen, and the majority of emissions occur during the cruise phase. International marine bunkers
 23 comprise emissions from fuels burned by ocean-going ships of all flags that are engaged in international transport.
 24 Ocean-going ships are generally classified as cargo and passenger carrying, military (i.e., U.S. Navy), fishing, and
 25 miscellaneous support ships (e.g., tugboats). For the purpose of estimating greenhouse gas emissions, international
 26 bunker fuels are solely related to cargo and passenger carrying vessels, which is the largest of the four categories,
 27 and military vessels. Two main types of fuels are used on sea-going vessels: distillate diesel fuel and residual fuel
 28 oil. Carbon dioxide is the primary greenhouse gas emitted from marine shipping.

29 Overall, aggregate greenhouse gas emissions in 2015 from the combustion of international bunker fuels from both
 30 aviation and marine activities were 111.8 MMT CO₂ Eq., or 7.0 percent above emissions in 1990 (see Table 3-63
 31 and Table 3-64). Emissions from international flights and international shipping voyages departing from the United
 32 States have increased by 88.8 percent and decreased by 40.6 percent, respectively, since 1990. The majority of these
 33 emissions were in the form of CO₂; however, small amounts of CH₄ (from marine transport modes) and N₂O were
 34 also emitted.

35 **Table 3-63: CO₂, CH₄, and N₂O Emissions from International Bunker Fuels (MMT CO₂ Eq.)**

Gas/Mode	1990	2005	2011	2012	2013	2014	2015
CO₂	103.5	113.1	111.7	105.8	99.8	103.2	110.8
Aviation	38.0	60.1	64.8	64.5	65.7	69.4	71.8
<i>Commercial</i>	30.0	55.6	61.7	61.4	62.8	66.3	68.6

3 Methodology

4 Emissions of CO₂ were estimated by applying C content and fraction oxidized factors to fuel consumption activity
5 data. This approach is analogous to that described under Section 3.1 – CO₂ from Fossil Fuel Combustion. Carbon
6 content and fraction oxidized factors for jet fuel, distillate fuel oil, and residual fuel oil were taken directly from EIA
7 and are presented in Annex 2.1, Annex 2.2, and Annex 3.8 of this Inventory. Density conversions were taken from
8 Chevron (2000), ASTM (1989), and USAF (1998). Heat content for distillate fuel oil and residual fuel oil were
9 taken from EIA (2016) and USAF (1998), and heat content for jet fuel was taken from EIA (2016). A complete
10 description of the methodology and a listing of the various factors employed can be found in Annex 2.1. See Annex
11 3.8 for a specific discussion on the methodology used for estimating emissions from international bunker fuel use by
12 the U.S. military.

13 Emission estimates for CH₄ and N₂O were calculated by multiplying emission factors by measures of fuel
14 consumption by fuel type and mode. Emission factors used in the calculations of CH₄ and N₂O emissions were
15 obtained from the 2006 IPCC Guidelines (IPCC 2006). For aircraft emissions, the following value, in units of grams
16 of pollutant per kilogram of fuel consumed (g/kg), was employed: 0.1 for N₂O (IPCC 2006). For marine vessels
17 consuming either distillate diesel or residual fuel oil the following values (g/MJ), were employed: 0.32 for CH₄ and
18 0.08 for N₂O. Activity data for aviation included solely jet fuel consumption statistics, while the marine mode
19 included both distillate diesel and residual fuel oil.

20 Activity data on domestic and international aircraft fuel consumption were developed by the U.S. Federal Aviation
21 Administration (FAA) using radar-informed data from the FAA Enhanced Traffic Management System (ETMS) for

1 1990, 2000 through 2015 as modeled with the Aviation Environmental Design Tool (AEDT). This bottom-up
 2 approach is built from modeling dynamic aircraft performance for each flight occurring within an individual
 3 calendar year. The analysis incorporates data on the aircraft type, date, flight identifier, departure time, arrival time,
 4 departure airport, arrival airport, ground delay at each airport, and real-world flight trajectories. To generate results
 5 for a given flight within AEDT, the radar-informed aircraft data is correlated with engine and aircraft performance
 6 data to calculate fuel burn and exhaust emissions. Information on exhaust emissions for in-production aircraft
 7 engines comes from the International Civil Aviation Organization (ICAO) Aircraft Engine Emissions Databank
 8 (EDB). This bottom-up approach is in accordance with the Tier 3B method from the *2006 IPCC Guidelines* (IPCC
 9 2006).

10 International aviation CO₂ estimates for 1990 and 2000 through 2015 are obtained from FAA’s AEDT model (FAA
 11 2017). The radar-informed method that was used to estimate CO₂ emissions for commercial aircraft for 1990, and
 12 2000 through 2015 is not possible for 1991 through 1999 because the radar data set is not available for years prior to
 13 2000. FAA developed OAG schedule-informed inventories modeled with AEDT and great circle trajectories for
 14 1990, 2000 and 2010. Because fuel consumption and CO₂ emission estimates for years 1991 through 1999 are
 15 unavailable, consumption estimates for these years were calculated using fuel consumption estimates from the
 16 Bureau of Transportation Statistics (DOT 1991 through 2013), adjusted based on 2000 through 2005 data.

17 Data on U.S. Department of Defense (DoD) aviation bunker fuels and total jet fuel consumed by the U.S. military
 18 was supplied by the Office of the Under Secretary of Defense (Installations and Environment), DoD. Estimates of
 19 the percentage of each Service’s total operations that were international operations were developed by DoD.
 20 Military aviation bunkers included international operations, operations conducted from naval vessels at sea, and
 21 operations conducted from U.S. installations principally over international water in direct support of military
 22 operations at sea. Military aviation bunker fuel emissions were estimated using military fuel and operations data
 23 synthesized from unpublished data from DoD’s Defense Logistics Agency Energy (DLA Energy 2016). Together,
 24 the data allow the quantity of fuel used in military international operations to be estimated. Densities for each jet
 25 fuel type were obtained from a report from the U.S. Air Force (USAF 1998). Final jet fuel consumption estimates
 26 are presented in Table 3-66. See Annex 3.8 for additional discussion of military data.

27 Activity data on distillate diesel and residual fuel oil consumption by cargo or passenger carrying marine vessels
 28 departing from U.S. ports were taken from unpublished data collected by the Foreign Trade Division of the U.S.
 29 Department of Commerce’s Bureau of the Census (DOC 2016) for 1990 through 2001, 2007 through 2015, and the
 30 Department of Homeland Security’s Bunker Report for 2003 through 2006 (DHS 2008). Fuel consumption data for
 31 2002 was interpolated due to inconsistencies in reported fuel consumption data. Activity data on distillate diesel
 32 consumption by military vessels departing from U.S. ports were provided by DLA Energy (2016). The total amount
 33 of fuel provided to naval vessels was reduced by 21 percent to account for fuel used while the vessels were not-
 34 underway (i.e., in port). Data on the percentage of steaming hours underway versus not-underway were provided by
 35 the U.S. Navy. These fuel consumption estimates are presented in Table 3-67.

36 **Table 3-66: Aviation Jet Fuel Consumption for International Transport (Million Gallons)**

Nationality	1990	2005	2011	2012	2013	2014	2015

Note: Totals may not sum due to independent rounding.

1 **Uncertainty and Time-Series Consistency – TO BE UPDATED**

2 **FOR FINAL INVENTORY REPORT**

3 Emission estimates related to the consumption of international bunker fuels are subject to the same uncertainties as
4 those from domestic aviation and marine mobile combustion emissions; however, additional uncertainties result
5 from the difficulty in collecting accurate fuel consumption activity data for international transport activities separate
6 from domestic transport activities.⁹⁵ For example, smaller aircraft on shorter routes often carry sufficient fuel to
7 complete several flight segments without refueling in order to minimize time spent at the airport gate or take
8 advantage of lower fuel prices at particular airports. This practice, called tankering, when done on international
9 flights, complicates the use of fuel sales data for estimating bunker fuel emissions. Tankering is less common with
10 the type of large, long-range aircraft that make many international flights from the United States, however. Similar
11 practices occur in the marine shipping industry where fuel costs represent a significant portion of overall operating
12 costs and fuel prices vary from port to port, leading to some tankering from ports with low fuel costs.

13 Uncertainties exist with regard to the total fuel used by military aircraft and ships, and in the activity data on military
14 operations and training that were used to estimate percentages of total fuel use reported as bunker fuel emissions.
15 Total aircraft and ship fuel use estimates were developed from DoD records, which document fuel sold to the Navy
16 and Air Force from the Defense Logistics Agency. These data may slightly over or under estimate actual total fuel
17 use in aircraft and ships because each Service may have procured fuel from, and/or may have sold to, traded with,
18 and/or given fuel to other ships, aircraft, governments, or other entities. There are uncertainties in aircraft operations
19 and training activity data. Estimates for the quantity of fuel actually used in Navy and Air Force flying activities
20 reported as bunker fuel emissions had to be estimated based on a combination of available data and expert judgment.
21 Estimates of marine bunker fuel emissions were based on Navy vessel steaming hour data, which reports fuel used
22 while underway and fuel used while not underway. This approach does not capture some voyages that would be
23 classified as domestic for a commercial vessel. Conversely, emissions from fuel used while not underway preceding
24 an international voyage are reported as domestic rather than international as would be done for a commercial vessel.
25 There is uncertainty associated with ground fuel estimates for 1997 through 2001. Small fuel quantities may have
26 been used in vehicles or equipment other than that which was assumed for each fuel type.

27 There are also uncertainties in fuel end-uses by fuel-type, emissions factors, fuel densities, diesel fuel sulfur content,
28 aircraft and vessel engine characteristics and fuel efficiencies, and the methodology used to back-calculate the data
29 set to 1990 using the original set from 1995. The data were adjusted for trends in fuel use based on a closely
30 correlating, but not matching, data set. All assumptions used to develop the estimate were based on process
31 knowledge, Department and military Service data, and expert judgments. The magnitude of the potential errors
32 related to the various uncertainties has not been calculated, but is believed to be small. The uncertainties associated
33 with future military bunker fuel emission estimates could be reduced through additional data collection.

34 Although aggregate fuel consumption data have been used to estimate emissions from aviation, the recommended
35 method for estimating emissions of gases other than CO₂ in the *2006 IPCC Guidelines* (IPCC 2006) is to use data by
36 specific aircraft type, number of individual flights and, ideally, movement data to better differentiate between
37 domestic and international aviation and to facilitate estimating the effects of changes in technologies. The IPCC also
38 recommends that cruise altitude emissions be estimated separately using fuel consumption data, while landing and
39 take-off (LTO) cycle data be used to estimate near-ground level emissions of gases other than CO₂.⁹⁶

⁹⁵ See uncertainty discussions under Carbon Dioxide Emissions from Fossil Fuel Combustion.

⁹⁶ U.S. aviation emission estimates for CO, NO_x, and NMVOCs are reported by EPA's National Emission Inventory (NEI) Air Pollutant Emission Trends website, and reported under the Mobile Combustion section. It should be noted that these estimates are based solely upon LTO cycles and consequently only capture near ground-level emissions, which are more relevant for air quality evaluations. These estimates also include both domestic and international flights. Therefore, estimates reported under the Mobile Combustion section overestimate IPCC-defined domestic CO, NO_x, and NMVOC emissions by including landing and take-off (LTO) cycles by aircraft on international flights, but underestimate because they do not include emissions from aircraft on domestic flight segments at cruising altitudes. The estimates in Mobile Combustion are also likely to include emissions from ocean-going vessels departing from U.S. ports on international voyages.

1 There is also concern regarding the reliability of the existing DOC (2016) data on marine vessel fuel consumption
 2 reported at U.S. customs stations due to the significant degree of inter-annual variation.

3 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 4 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 5 above.

6 QA/QC and Verification

7 A source-specific QA/QC plan for international bunker fuels was developed and implemented. This effort included a
 8 Tier 1 analysis, as well as portions of a Tier 2 analysis. The Tier 2 procedures that were implemented involved
 9 checks specifically focusing on the activity data and emission factor sources and methodology used for estimating
 10 CO₂, CH₄, and N₂O from international bunker fuels in the United States. Emission totals for the different sectors and
 11 fuels were compared and trends were investigated. No corrective actions were necessary.

12 Planned Improvements

13 The feasibility of including data from a broader range of domestic and international sources for bunker fuels,
 14 including data from studies such as the *Third IMO GHG Study 2014* (IMO 2014), is being considered.

15 3.10 Wood Biomass and Ethanol

16 Consumption (IPCC Source Category 1A)

17 The combustion of biomass fuels such as wood, charcoal, and wood waste and biomass-based fuels such as ethanol,
 18 biogas, and biodiesel generates CO₂ in addition to CH₄ and N₂O already covered in this chapter. In line with the
 19 reporting requirements for inventories submitted under the UNFCCC, CO₂ emissions from biomass combustion
 20 have been estimated separately from fossil fuel CO₂ emissions and are not directly included in the energy sector
 21 contributions to U.S. totals. In accordance with IPCC methodological guidelines, any such emissions are calculated
 22 by accounting for net carbon (C) fluxes from changes in biogenic C reservoirs in wooded or crop lands. For a more
 23 complete description of this methodological approach, see the Land Use, Land-Use Change, and Forestry chapter
 24 (Chapter 6), which accounts for the contribution of any resulting CO₂ emissions to U.S. totals within the Land Use,
 25 Land-Use Change, and Forestry sector's approach.

26 In 2015, total CO₂ emissions from the burning of woody biomass in the industrial, residential, commercial, and
 27 electricity generation sectors were approximately 198.7 MMT CO₂ Eq. (198,723 kt) (see Table 3-68 and Table
 28 3-69). As the largest consumer of woody biomass, the industrial sector was responsible for 61.2 percent of the CO₂
 29 emissions from this source. The residential sector was the second largest emitter, constituting 22.4 percent of the
 30 total, while the commercial and electricity generation sectors accounted for the remainder.

31 **Table 3-68: CO₂ Emissions from Wood Consumption by End-Use Sector (MMT CO₂ Eq.)**

End-Use Sector	1990	2005	2011	2012	2013	2014	2015
Industrial	135.3	136.3	122.9	125.7	123.1	124.4	121.6

Note: Totals may not sum due to independent rounding.

1 The transportation sector is responsible for most of the ethanol consumption in the United States. Ethanol is
2 currently produced primarily from corn grown in the Midwest, but it can be produced from a variety of biomass
3 feedstocks. Most ethanol for transportation use is blended with gasoline to create a 90 percent gasoline, 10 percent
4 by volume ethanol blend known as E-10 or gasohol.

5 In 2015, the United States consumed an estimated 1,153.1 trillion Btu of ethanol, and as a result, produced
6 approximately 78.9 MMT CO₂ Eq. (78,934 kt) (see Table 3-70 and Table 3-71) of CO₂ emissions. Ethanol
7 production and consumption has grown significantly since 1990 due to the favorable economics of blending ethanol
8 into gasoline and federal policies that have encouraged use of renewable fuels.

9 **Table 3-70: CO₂ Emissions from Ethanol Consumption (MMT CO₂ Eq.)**

^a See Annex 3.2, Table A-94 for additional information on transportation consumption of these fuels.

Note: Totals may not sum due to independent rounding.

11 Methodology

12 Woody biomass emissions were estimated by applying two EIA gross heat contents (Lindstrom 2006) to U.S.
13 consumption data (EIA 2016) (see Table 3-72), provided in energy units for the industrial, residential, commercial,
14 and electric generation sectors. One heat content (16.95 MMBtu/MT wood and wood waste) was applied to the
15 industrial sector's consumption, while the other heat content (15.43 MMBtu/MT wood and wood waste) was applied
16 to the consumption data for the other sectors. An EIA emission factor of 0.434 MT C/MT wood (Lindstrom 2006)
17 was then applied to the resulting quantities of woody biomass to obtain CO₂ emission estimates. It was assumed that
18 the woody biomass contains black liquor and other wood wastes, has a moisture content of 12 percent, and is
19 converted into CO₂ with 100 percent efficiency. The emissions from ethanol consumption were calculated by
20 applying an emission factor of 18.7 MMT C/QBtu (EPA 2010) to U.S. ethanol consumption estimates that were
21 provided in energy units (EIA 2016) (see Table 3-73).

1 **Table 3-72: Woody Biomass Consumption by Sector (Trillion Btu)**

End-Use Sector	1990	2005	2011	2012	2013	2014	2015
Industrial	1,441.9	1,451.7	1,308.9	1,339.4	1,312.0	1,325.0	1,295.1
Residential	580.0	430.0	450.0	420.0	580.0	580.0	431.5
Commercial	65.7	70.0	69.2	60.7	70.2	73.4	72.9

Commercial	0.5	0.9	2.9	2.6	2.7	4.1	4.2
Total	61.7	335.1	1,064.6	1,063.8	1,091.8	1,111.3	1,153.1

Note: Totals may not sum due to independent rounding.

3 **Uncertainty and Time-Series Consistency – TO BE UPDATED**

4 **FOR FINAL INVENTORY REPORT**

5 It is assumed that the combustion efficiency for woody biomass is 100 percent, which is believed to be an
6 overestimate of the efficiency of wood combustion processes in the United States. Decreasing the combustion
7 efficiency would decrease emission estimates. Additionally, the heat content applied to the consumption of woody
8 biomass in the residential, commercial, and electric power sectors is unlikely to be a completely accurate
9 representation of the heat content for all the different types of woody biomass consumed within these sectors.
10 Emission estimates from ethanol production are more certain than estimates from woody biomass consumption due
11 to better activity data collection methods and uniform combustion techniques.

12 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
13 through 2014. Details on the emission trends through time are described in more detail in the Methodology section,
14 above.

15 **Recalculations Discussion**

16 Wood consumption values for 2014 were not revised relative to the previous Inventory, as there were no historical
17 revisions from EIA's *Monthly Energy Review* (EIA 2016).

18 **Planned Improvements**

19 The availability of facility-level combustion emissions through EPA's Greenhouse Gas Reporting Program
20 (GHGRP) will be examined to help better characterize the industrial sector's energy consumption in the United
21 States, and further classify woody biomass consumption by business establishments according to industrial
22 economic activity type. Most methodologies used in EPA's GHGRP are consistent with IPCC, though for EPA's
23 GHGRP, facilities collect detailed information specific to their operations according to detailed measurement
24 standards, which may differ with the more aggregated data collected for the Inventory to estimate total, national U.S.
25 emissions. In addition, and unlike the reporting requirements for this chapter under the UNFCCC reporting
26 guidelines, some facility-level fuel combustion emissions reported under the GHGRP may also include industrial
27 process emissions.⁹⁷ In line with UNFCCC reporting guidelines, fuel combustion emissions are included in this
28 chapter, while process emissions are included in the Industrial Processes and Product Use chapter of this report. In

⁹⁷ See <<http://unfccc.int/resource/docs/2006/sbsta/eng/09.pdf>>.

1 examining data from EPA’s GHGRP that would be useful to improve the emission estimates for the CO₂ from
2 biomass combustion category, particular attention will also be made to ensure time series consistency, as the
3 facility-level reporting data from EPA’s GHGRP are not available for all inventory years as reported in this
4 Inventory. Additionally, analyses will focus on aligning reported facility-level fuel types and IPCC fuel types per the
5 national energy statistics, ensuring CO₂ emissions from biomass are separated in the facility-level reported data, and
6 maintaining consistency with national energy statistics provided by EIA. In implementing improvements and
7 integration of data from EPA’s GHGRP, the latest guidance from the IPCC on the use of facility-level data in
8 national inventories will be relied upon.⁹⁸

9 Currently emission estimates from biomass and biomass based fuels included in this inventory are limited to woody
10 biomass and ethanol. Other forms of biomass-based fuel consumption include biogas and biodiesel. An effort will be
11 made to examine sources of data for biogas and biodiesel including data from EIA for possible inclusion. EIA
12 (2016) natural gas data deducts biogas used in the natural gas supply. EIA (2016) diesel data does not deduct for
13 biodiesel, so the fuel consumption data must subtract biodiesel consumption.

⁹⁸ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

4. Industrial Processes and Product Use

The Industrial Processes and Product Use (IPPU) chapter includes greenhouse gas emissions occurring from industrial processes and from the use of greenhouse gases in products. The industrial processes and product use categories included in this chapter are presented in Figure 4-1.

Greenhouse gas emissions are produced as the byproducts of various non-energy-related industrial activities. That is, these emissions are produced either from an industrial process itself, and are not directly a result of energy consumed during the process. For example, raw materials can be chemically or physically transformed from one state to another. This transformation can result in the release of greenhouse gases such as carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O). The processes included in this chapter include iron and steel production and metallurgical coke production, cement production, lime production, other process uses of carbonates (e.g., flux stone, flue gas desulfurization, and glass manufacturing), ammonia production and urea consumption, petrochemical production, aluminum production, soda ash production and use, titanium dioxide production, CO₂ consumption, ferroalloy production, glass production, zinc production, phosphoric acid production, lead production, silicon carbide production and consumption, nitric acid production, and adipic acid production.

In addition, greenhouse gases are often used in products or by end-consumers. These gases include industrial sources of man-made compounds such as hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), sulfur hexafluoride (SF₆), nitrogen trifluoride (NF₃), as well as N₂O. The present contribution of HFCs, PFCs, SF₆, and NF₃ gases to the radiative forcing effect of all anthropogenic greenhouse gases is small; however, because of their extremely long lifetimes, many of them will continue to accumulate in the atmosphere as long as emissions continue. In addition, many of these gases have high global warming potentials; SF₆ is the most potent greenhouse gas the Intergovernmental Panel on Climate Change (IPCC) has evaluated. Use of HFCs is growing rapidly since they are the primary substitutes for ozone depleting substances (ODSs), which are being phased-out under the Montreal Protocol on Substances that Deplete the Ozone Layer. Hydrofluorocarbons, PFCs, SF₆, and NF₃ are employed and emitted by a number of other industrial sources in the United States such as aluminum production, HCFC-22 production, semiconductor manufacture, electric power transmission and distribution, and magnesium metal production and processing. Nitrous oxide is emitted by the production of adipic acid and nitric acid, semiconductor manufacturing, end-consumers in product uses through the administration of anesthetics, and by industry as a propellant in aerosol products.

In 2015, IPPU generated emissions of 375.1 million metric tons of CO₂ equivalent (MMT CO₂ Eq.), or 5.7 percent of total U.S. greenhouse gas emissions. Carbon dioxide emissions from all industrial processes were 169.0 MMT CO₂ Eq. (168,956 kt CO₂) in 2015, or 3.1 percent of total U.S. CO₂ emissions. Methane emissions from industrial processes resulted in emissions of approximately 0.2 MMT CO₂ Eq. (9 kt CH₄) in 2015, which was less than 1 percent of U.S. CH₄ emissions. Nitrous oxide emissions from IPPU were 20.3 MMT CO₂ Eq. (68 kt N₂O) in 2015, or 6.1 percent of total U.S. N₂O emissions. In 2015 combined emissions of HFCs, PFCs, SF₆, and NF₃ totaled 185.6 MMT CO₂ Eq. Total emissions from IPPU in 2015 were 10.9 percent more than 1990 emissions. Indirect greenhouse gas emissions also result from IPPU, and are presented in Table 4-107 in kilotons (kt).

1 **Figure 4-1: 2015 Industrial Processes and Product Use Chapter Greenhouse Gas Sources**
 2 **(MMT CO₂ Eq.)**

3
 4
 5 The increase in overall IPPU emissions since 1990 reflects a range of emission trends among the emission sources.
 6 Emissions resulting from most types of metal production have declined significantly since 1990, largely due to
 7 production shifting to other countries, but also due to transitions to less-emissive methods of production (in the case
 8 of iron and steel) and to improved practices (in the case of PFC emissions from aluminum production). Emissions
 9 from mineral sources have either increased or not changed significantly since 1990 but largely track economic
 10 cycles, while CO₂ and CH₄ emissions from chemical sources have either decreased or not changed significantly.
 11 Hydrofluorocarbon emissions from the substitution of ODS have increased drastically since 1990, while the
 12 emission trends of HFCs, PFCs, SF₆, and NF₃ from other sources are mixed. Nitrous oxide emissions from the
 13 production of adipic and nitric acid have decreased, while N₂O emissions from product uses has remained nearly
 14 constant over time. Trends are explained further within each emission source category throughout the chapter.

15 Table 4-1 summarizes emissions for the IPPU chapter in MMT CO₂ Eq. using *IPCC Fourth Assessment Report*
 16 (AR4) GWP values, following the requirements of the revised United Nations Framework Convention on Climate
 17 Change (UNFCCC) reporting guidelines for national inventories (IPCC 2007).¹ Unweighted native gas emissions in
 18 kt are also provided in Table 4-2. The source descriptions that follow in the chapter are presented in the order as
 19 reported to the UNFCCC in the common reporting format tables, corresponding generally to: mineral products,
 20 chemical production, metal production, and emissions from the uses of HFCs, PFCs, SF₆, and NF₃.

1
2 The UNFCCC incorporated the *2006 IPCC Guidelines for National Greenhouse Gas Inventories (2006 IPCC*
3 *Guidelines)* as the standard for Annex I countries at the Nineteenth Conference of the Parties (Warsaw, November
4 11-23, 2013). This chapter presents emission estimates calculated in accordance with the methodological guidance
5 provided in these guidelines.

6 QA/QC and Verification Procedures – TO BE UPDATED FOR 7 FINAL INVENTORY REPORT

8 For industrial processes and product use sources, a detailed QA/QC plan was developed and implemented for
9 specific categories. This plan was based on the overall The Quality Assurance/Quality Control and Uncertainty
10 Management Plan for the U.S. Greenhouse Gas Inventory (QA/QC Management Plan), but was tailored to include
11 specific procedures recommended for these sources. Two types of checks were performed using this plan: (1)
12 general, or Tier 1, procedures consistent with Volume 1, Chapter 6 of the 2006 IPCC GL that focus on annual
13 procedures and checks to be used when gathering, maintaining, handling, documenting, checking, and archiving the
14 data, supporting documents, and files; and (2) source-category specific, or Tier 2, procedures that focus on checks
15 and comparisons of the emission factors, activity data, and methodologies used for estimating emissions from the
16 relevant industrial process and product use sources. Examples of these procedures include checks to ensure that
17 activity data and emission estimates are consistent with historical trends; that, where possible, consistent and
18 reputable data sources are used across sources; that interpolation or extrapolation techniques are consistent across
19 sources; and that common datasets and factors are used where applicable. Tier 1 quality assurance and quality
20 control procedures and calculation-related QC (category-specific, Tier 2) have been performed for all industrial
21 process and product use sources. Additional Tier 2 procedures were performed for more significant emission
22 categories or sources where significant methodological and data updates have taken place, consistent with the *IPCC*
23 *Good Practice Guidelines*. Application of these procedures and updates/improvements as a result of QA processes
24 (expert, public, and UNFCCC technical expert reviews) are described further within respective source categories,
25 such as ODS Substitutes in dedicated comparison sections, or the recalculations, and planned improvement sections.

26 For most industrial process and product use categories, activity data is obtained via aggregation of facility level data
27 from EPA's Greenhouse Gas Reporting Program, national commodity surveys conducted by U.S. Geologic Survey
28 Mineral's Information Center, U.S. Department of Energy (DOE), U.S. Census Bureau, industry associations such
29 as Air-Conditioning, Heating, and Refrigeration Institute (AHRI), American Chemistry Council (ACC), and
30 American Iron and Steel Institute, (specified within each source); the uncertainty of the activity data is a function of
31 the reliability of reported plant-level production data and is influenced by the completeness of the survey response.
32 The emission factors used are derived from EPA GHGRP, application of IPCC defaults. IPCC default factors are
33 derived using calculations that assume precise and efficient chemical reactions, or were based upon empirical data in
34 published references. As a result, uncertainties in the emission coefficients can be attributed to, among other things,
35 inefficiencies in the chemical reactions associated with each production process or to the use of empirically-derived
36 emission factors that are biased; therefore, they may or may not represent U.S. national averages. Additional
37 assumptions are described within each source.

38 The uncertainty analysis performed to quantify uncertainties associated with the 2015 emission estimates from
39 industrial processes and product use continues a multi-year process for developing credible quantitative uncertainty

1 estimates for these source categories using the IPCC Tier 2 approach. As the process continues, the type and the
2 characteristics of the actual probability density functions underlying the input variables are identified and better
3 characterized (resulting in development of more reliable inputs for the model, including accurate characterization of
4 correlation between variables), based primarily on expert judgment. Accordingly, the quantitative uncertainty
5 estimates reported in this section should be considered illustrative and as iterations of ongoing efforts to produce
6 accurate uncertainty estimates. The correlation among data used for estimating emissions for different sources can
7 influence the uncertainty analysis of each individual source. While the uncertainty analysis recognizes very
8 significant connections among sources, a more comprehensive approach that accounts for all linkages will be
9 identified as the uncertainty analysis moves forward.

10 **Box 4-1: Industrial Processes Data from EPA's Greenhouse Gas Reporting Program**

11 On October 30, 2009, the U.S. Environmental Protection Agency (EPA) published a rule requiring annual reporting
12 of greenhouse gas data from large greenhouse gas emissions sources in the United States. Implementation of the
13 rule, codified at 40 CFR part 98, is referred to as EPA's Greenhouse Gas Reporting Program (GHGRP). The rule
14 applies to direct greenhouse gas emitters, fossil fuel suppliers, industrial gas suppliers, and facilities that inject CO₂
15 underground for sequestration or other reasons and requires reporting by sources or suppliers in 41 industrial
16 categories. Annual reporting is at the facility level, except for certain suppliers of fossil fuels and industrial
17 greenhouse gases. In general, the threshold for reporting is 25,000 metric tons or more of CO₂ Eq. per year, but
18 reporting is required for all facilities in some industries. Calendar year 2010 was the first year for which data were
19 reported for facilities subject to 40 CFR part 98, though some source categories first reported data for calendar year
20 2011.

21 EPA's GHGRP dataset and the data presented in this Inventory are complementary. EPA presents the data collected
22 by EPA's GHGRP through a data publication tool (ghgdata.epa.gov) that allows data to be viewed in several
23 formats, including maps, tables, charts, and graphs for individual facilities or groups of facilities. Most
24 methodologies used in EPA's GHGRP are consistent with IPCC, though for EPA's GHGRP, facilities collect
25 detailed information specific to their operations according to detailed measurement standards. This may differ from
26 the more aggregated data collected for the Inventory to estimate total, national U.S. emissions. It should be noted
27 that the definitions for source categories in EPA's GHGRP may differ from those used in this Inventory in meeting
28 the UNFCCC reporting guidelines (IPCC 2011). In line with the UNFCCC reporting guidelines, the Inventory is a
29 comprehensive accounting of all emissions from source categories identified in the IPCC (2006) guidelines. Further
30 information on the reporting categorizations in EPA's GHGRP and specific data caveats associated with monitoring
31 methods in EPA's GHGRP has been provided on the EPA's GHGRP website.

32 For certain source categories in this Inventory (e.g., nitric acid production and petrochemical production), EPA has
33 also integrated data values that have been calculated by aggregating EPA's GHGRP data that are considered
34 confidential business information (CBI) at the facility level. EPA, with industry engagement, has put forth criteria to
35 confirm that a given data aggregation shields underlying CBI from public disclosure. EPA is publishing only data
36 values that meet these aggregation criteria.² Specific uses of aggregated facility-level data are described in the
37 respective methodological sections. For other source categories in this chapter, as indicated in the respective planned
38 improvements sections, EPA is continuing to analyze how facility-level GHGRP data may be used to improve the
39 national estimates presented in this Inventory, giving particular consideration to ensuring time series consistency and
40 completeness. As stated previously in the Introduction chapter, this year EPA has integrated GHGRP information
41 for various Industrial Processes and Product Use categories³ and also identified places where EPA plans to integrate
42 additional GHGRP data in additional categories⁴ (see those categories Planned Improvement sections for details).
43 The GHGRP dataset is a particularly important annual resource and will continue to be important for improving
44 emissions estimates from Industrial Process and Product Use in future Inventory reports.

² U.S. EPA Greenhouse Gas Reporting Program. Developments on Publication of Aggregated Greenhouse Gas Data, November 25, 2014. See <<http://www.epa.gov/ghgreporting/confidential-business-information-ghg-reporting>>.

³ Adipic Acid Production, Aluminum Production, Carbon Dioxide Consumption, Electrical Transmission and Distribution, HCFC-22 Production, Lime Production, Magnesium Production and Processing, ODS Substitutes, Nitric Acid Production, Petrochemical Production, and Semiconductor Manufacture.

⁴ Ammonia Production, Cement Production, Glass Production and Other fluorinated gas production.

4.1 Cement Production (IPCC Source Category 2A1)

Cement production is an energy- and raw material-intensive process that results in the generation of carbon dioxide (CO₂) from both the energy consumed in making the cement and the chemical process itself. Emissions from fuels consumed for energy purposes during the production of cement are accounted for in the Energy chapter.

During the cement production process, calcium carbonate (CaCO₃) is heated in a cement kiln at a temperature of about 1,450 degrees Celsius (2,700 degrees Fahrenheit) to form lime (i.e., calcium oxide or CaO) and CO₂ in a process known as calcination or calcining. The quantity of CO₂ emitted during cement production is directly proportional to the lime content of the clinker. During calcination, each mole of limestone (CaCO₃) heated in the clinker kiln forms one mole of lime (CaO) and one mole of CO₂:

Next, the lime is combined with silica-containing materials to produce clinker (an intermediate product), with the earlier byproduct CO₂ being released to the atmosphere. The clinker is then allowed to cool, mixed with a small amount of gypsum and potentially other materials (e.g., slag, etc.), and used to make Portland cement.⁵

Carbon dioxide emitted from the chemical process of cement production is the second largest source of industrial CO₂ emissions in the United States. Cement is produced in 34 states and Puerto Rico. Texas, California, Missouri, Florida, and Alabama were the five leading cement-producing states in 2015 and accounted for nearly 50 percent of total U.S. production (USGS 2016b). Clinker production in 2015 increased approximately 2 percent from 2014 levels as cement sales continued to increase in 2015, but at a more moderate rate compared to 2014. In 2015, U.S. clinker production totaled 76,555 kilotons (USGS 2016a). The resulting CO₂ emissions were estimated to be 39.6 MMT CO₂ Eq. (39,587 kt) (see Table 4-3).

Table 4-3: CO₂ Emissions from Cement Production (MMT CO₂ Eq. and kt)

Year	MMT CO ₂ Eq.	kt
1990	33.3	33,278
2005	45.9	45,910
2011	32.0	32,010
2012	35.1	35,053
2013	36.1	36,145
2014	38.8	38,789
2015	39.6	39,587

Greenhouse gas emissions from cement production increased every year from 1991 through 2006 (with the exception of a slight decrease in 1997), but decreased in the following years until 2009. Emissions from cement production were at their lowest levels in 2009 (2009 emissions are approximately 28 percent lower than 2008 emissions and 12 percent lower than 1990). Since 2010, emissions have increased by roughly 27 percent. In 2015, emissions from cement production increased by 2 percent from 2014 levels.

⁵ Approximately three percent of total clinker production is used to produce masonry cement, which is produced using plasticizers (e.g., ground limestone, lime, etc.) and Portland cement (USGS 2011). Carbon dioxide emissions that result from the production of lime used to create masonry cement are included in the Lime Manufacture source category.

1 Emissions since 1990 have increased by 19 percent. Emissions decreased significantly between 2008 and 2009, due
 2 to the economic recession and associated decrease in demand for construction materials. Emissions increased
 3 slightly from 2009 levels in 2010, and continued to gradually increase during the 2011 through 2015 time period due
 4 to increasing consumption. Cement continues to be a critical component of the construction industry; therefore, the
 5 availability of public and private construction funding, as well as overall economic conditions, have considerable
 6 impact on the level of cement production.

7 Methodology

8 Carbon dioxide emissions were estimated using the Tier 2 methodology from the *2006 IPCC Guidelines*. The Tier 2
 9 methodology was used because detailed and complete data (including weights and composition) for carbonate(s)
 10 consumed in clinker production are not available, and thus a rigorous Tier 3 approach is impractical. Tier 2 specifies
 11 the use of aggregated plant or national clinker production data and an emission factor, which is the product of the
 12 average lime fraction for clinker of 65 percent and a constant reflecting the mass of CO₂ released per unit of lime.
 13 The U.S. Geological Survey (USGS) mineral commodity expert for cement has confirmed that this is a reasonable
 14 assumption for the United States (Van Oss 2013a). This calculation yields an emission factor of 0.51 tons of CO₂ per
 15 ton of clinker produced, which was determined as follows:

$$16 \quad EF_{\text{clinker}} = 0.6460 \text{ CaO} \times [(44.01 \text{ g/mole CO}_2) \div (56.08 \text{ g/mole CaO})] = 0.5070 \text{ tons CO}_2/\text{ton clinker}$$

17 During clinker production, some of the clinker precursor materials remain in the kiln as non-calcinated, partially
 18 calcinated, or fully calcinated cement kiln dust (CKD). The emissions attributable to the calcinated portion of the
 19 CKD are not accounted for by the clinker emission factor. The IPCC recommends that these additional CKD CO₂
 20 emissions should be estimated as two percent of the CO₂ emissions calculated from clinker production (when data
 21 on CKD generation are not available). Total cement production emissions were calculated by adding the emissions
 22 from clinker production to the emissions assigned to CKD (IPCC 2006).

23 Furthermore, small amounts of impurities (i.e., not calcium carbonate) may exist in the raw limestone used to
 24 produce clinker. The proportion of these impurities is generally minimal, although a small amount (1 to 2 percent) of
 25 magnesium oxide (MgO) may be desirable as a flux. Per the IPCC Tier 2 methodology, a correction for MgO is not
 26 used, since the amount of MgO from carbonate is likely very small and the assumption of a 100 percent carbonate
 27 source of CaO already yields an overestimation of emissions (IPCC 2006). The 1990 through 2012 activity data for
 28 clinker production (see Table 4-4) were obtained from USGS (Van Oss 2013b). Clinker production data for 2013
 29 through 2015 were also obtained from USGS (USGS 2016a). The data were compiled by USGS (to the nearest ton)
 30 through questionnaires sent to domestic clinker and cement manufacturing plants, including the facilities in Puerto
 31 Rico.

32 **Table 4-4: Clinker Production (kt)**

Year	Clinker
1990	64,355
2005	88,783
2011	61,903
2012	67,788
2013	69,900
2014	75,012
2015	76,555

Notes: Clinker production from 1990 through 2015 includes Puerto Rico. Data were obtained from USGS (Van Oss 2013a; USGS 2016), whose original data source was USGS and U.S. Bureau of Mines Minerals Yearbooks (2014 data obtained from mineral industry surveys for cement in September 2015; 2015 data obtained from mineral industry surveys for cement in January 2016).

Uncertainty and Time-Series Consistency – TO BE UPDATED FOR FINAL INVENTORY REPORT

The uncertainties contained in these estimates are primarily due to uncertainties in the lime content of clinker and in the percentage of CKD recycled inside the cement kiln. Uncertainty is also associated with the assumption that all calcium-containing raw materials are CaCO₃, when a small percentage likely consists of other carbonate and non-carbonate raw materials. The lime content of clinker varies from 60 to 67 percent; 65 percent is used as a representative value (Van Oss 2013a). CKD loss can range from 1.5 to 8 percent depending upon plant specifications. Additionally, some amount of CO₂ is reabsorbed when the cement is used for construction. As cement reacts with water, alkaline substances such as calcium hydroxide are formed. During this curing process, these compounds may react with CO₂ in the atmosphere to create calcium carbonate. This reaction only occurs in roughly the outer 0.2 inches of surface area. Because the amount of CO₂ reabsorbed is thought to be minimal, it was not estimated.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-5. Based on the uncertainties associated with total U.S. clinker production, the CO₂ emission factor for clinker production, and the emission factor for additional CO₂ emissions from CKD, 2015 CO₂ emissions from cement production were estimated to be between 37.2 and 42.0 MMT CO₂ Eq. at the 95 percent confidence level. This confidence level indicates a range of approximately 6 percent below and 6 percent above the emission estimate of 39.6 MMT CO₂ Eq.

Table 4-5: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Cement Production (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Cement Production	CO ₂	39.6	37.2	42.0	-6%	+6%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Planned Improvements

In response to comments from the Portland Cement Association (PCA) during the prior public review and UNFCCC expert technical reviews, EPA is continuing to evaluate and analyze data reported under EPA's GHGRP that would be useful to improve the emission estimates for the Cement Production source category. EPA held a technical meeting with PCA in August 2016 to review inventory methods and available data from the GHGRP data set. Most cement production facilities reporting under EPA's GHGRP use Continuous Emission Monitoring Systems (CEMS) to monitor and report CO₂ emissions, thus reporting combined process and combustion emissions from kilns. In the near-term, EPA will assess use of aggregated activity data on clinker production, reported by all facilities starting in calendar year 2014, first reported to EPA in March 2015. In assessing use of this and other data from EPA's GHGRP, particular attention will be made to ensure time series consistency of the emissions estimates presented in future Inventory reports, consistent with IPCC and UNFCCC guidelines. This is required as facility-level reporting data from EPA's GHGRP, with the program's initial requirements for reporting of emissions in calendar year 2010, are not available for all inventory years (i.e., 1990 through 2009) as required for this Inventory. This will be documented along with application of category-specific QC to compare activity data from GHGRP with existing data from USGS. In implementing improvements and integration of data from EPA's GHGRP, the latest guidance from the IPCC on the use of facility-level data in national inventories will be relied upon, in addition to category

1 specific QC methods recommended by 2006 IPCC Guidelines.⁶ EPA’s long-term improvement plan includes
 2 continued assessment and feasibility to use additional GHGRP information, in particular disaggregating aggregated
 3 GHGRP emissions consistent with IPCC and UNFCCC guidelines to present both national process and combustion
 4 emissions streams. This longer-term planned analysis is still in development and has not been updated for this
 5 current inventory report.

6 4.2 Lime Production (IPCC Source Category 7 2A2)

8 Lime is an important manufactured product with many industrial, chemical, and environmental applications. Lime
 9 production involves three main processes: stone preparation, calcination, and hydration. Carbon dioxide (CO₂) is
 10 generated during the calcination stage, when limestone—mostly calcium carbonate (CaCO₃)—is roasted at high
 11 temperatures in a kiln to produce calcium oxide (CaO) and CO₂. The CO₂ is given off as a gas and is normally
 12 emitted to the atmosphere.

13
 14 Some of the CO₂ generated during the production process, however, is recovered at some facilities for use in sugar
 15 refining and precipitated calcium carbonate (PCC) production.⁷ Emissions from fuels consumed for energy purposes
 16 during the production of lime are accounted for in the Energy chapter.

17 For U.S. operations, the term “lime” actually refers to a variety of chemical compounds. These include CaO, or
 18 high-calcium quicklime; calcium hydroxide (Ca(OH)₂), or hydrated lime; dolomitic quicklime ([CaO•MgO]); and
 19 dolomitic hydrate ([Ca(OH)₂•MgO] or [Ca(OH)₂•Mg(OH)₂]).

20 The current lime market is approximately distributed across five end-use categories as follows: metallurgical uses,
 21 37 percent; environmental uses, 31 percent; chemical and industrial uses, 22 percent; construction uses, 9 percent;
 22 and refractory dolomite, 1 percent (USGS 2016b). The major uses are in steel making, flue gas desulfurization
 23 systems at coal-fired electric power plants, construction, and water treatment, as well as uses in mining, pulp and
 24 paper and precipitated calcium carbonate manufacturing. Lime is also used as a CO₂ scrubber, and there has been
 25 experimentation on the use of lime to capture CO₂ from electric power plants.

26 Lime production in the United States—including Puerto Rico—was reported to be 18,279 kilotons in 2015
 27 (Corathers 2017). At year-end 2015, there were 77 operating primary lime plants in the United States, including
 28 Puerto Rico⁸. Principal lime producing states are Missouri, Alabama, Kentucky, Ohio, Texas (USGS 2016a).

29 U.S. lime production resulted in estimated net CO₂ emissions of 13.3 MMT CO₂ Eq. (13,342 kt) (see Table 4-6 and
 30 Table 4-7). The trends in CO₂ emissions from lime production are directly proportional to trends in production,
 31 which are described below.

32 **Table 4-6: CO₂ Emissions from Lime Production (MMT CO₂ Eq. and kt)**

Year	MMT CO ₂ Eq.	kt
1990	11.7	11,700
2005	14.6	14,552
2011	14.0	13,982

⁶ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

⁷ PCC is obtained from the reaction of CO₂ with calcium hydroxide. It is used as a filler and/or coating in the paper, food, and plastic industries.

⁸ In 2015, 74 operating primary lime facilities in the United States reported to the EPA Greenhouse Gas Reporting Program.

2012	13.8	13,785
2013	14.0	14,028
2014	14.2	14,210
2015	13.3	13,342

1 **Table 4-7: Potential, Recovered, and Net CO₂ Emissions from Lime Production (kt)**

Year	Potential	Recovered ^a	Net Emissions
1990	11,959	259	11,700
2005	15,074	522	14,552
2011	14,389	407	13,982
2012	14,258	473	13,785
2013	14,495	467	14,028
2014	14,715	505	14,210
2015	13,764	422	13,342

^a For sugar refining and PCC production.

Note: Totals may not sum due to independent rounding.

2 In 2015, lime production decreased compared to 2014 levels (decrease of about 6 percent) at 18,279 kilotons, owing
3 to decreased consumption by the U.S. nonferrous metallurgical industries (primarily copper) and steel industries
4 (Corathers 2017; USGS 2016a).

5 Methodology

6 To calculate emissions, the amounts of high-calcium and dolomitic lime produced were multiplied by their
7 respective emission factors using the Tier 2 approach from the *2006 IPCC Guidelines*. The emission factor is the
8 product of the stoichiometric ratio between CO₂ and CaO, and the average CaO and MgO content for lime. The CaO
9 and MgO content for lime is assumed to be 95 percent for both high-calcium and dolomitic lime (IPCC 2006). The
10 emission factors were calculated as follows:

11 For high-calcium lime:

$$12 \quad [(44.01 \text{ g/mole CO}_2) \div (56.08 \text{ g/mole CaO})] \times (0.9500 \text{ CaO/lime}) = 0.7455 \text{ g CO}_2/\text{g lime}$$

13 For dolomitic lime:

$$14 \quad [(88.02 \text{ g/mole CO}_2) \div (96.39 \text{ g/mole CaO})] \times (0.9500 \text{ CaO/lime}) = 0.8675 \text{ g CO}_2/\text{g lime}$$

15 Production was adjusted to remove the mass of chemically combined water found in hydrated lime, determined
16 according to the molecular weight ratios of H₂O to (Ca(OH)₂ and [Ca(OH)₂•Mg(OH)₂]) (IPCC 2006). These factors
17 set the chemically combined water content to 24.3 percent for high-calcium hydrated lime, and 27.2 percent for
18 dolomitic hydrated lime.

19 The *2006 IPCC Guidelines* (Tier 2 method) also recommends accounting for emissions from lime kiln dust (LKD)
20 through application of a correction factor. LKD is a byproduct of the lime manufacturing process typically not
21 recycled back to kilns. LKD is a very fine-grained material and is especially useful for applications requiring very
22 small particle size. Most common LKD applications include soil reclamation and agriculture. Currently, data on
23 annual LKD production is not readily available to develop a country specific correction factor. Lime emission
24 estimates were multiplied by a factor of 1.02 to account for emissions from LKD (IPCC 2006). See the Planned
25 Improvements section associated with efforts to improve uncertainty analysis and emission estimates associated with
26 LKD.

27 Lime emission estimates were further adjusted to account for the amount of CO₂ captured for use in on-site
28 processes. All the domestic lime facilities are required to report these data to EPA under its GHGRP. The total
29 national-level annual amount of CO₂ captured for on-site process use was obtained from EPA's GHGRP (EPA

1 2016) based on reported facility level data for years 2010 through 2015. The amount of CO₂ captured/recovered for
 2 on-site process use is deducted from the total potential emissions (i.e., from lime production and LKD). The net lime
 3 emissions are presented in Table 4-6 and Table 4-7. GHGRP data on CO₂ removals (i.e., CO₂ captured/recovered)
 4 was available only for 2010 through 2015. Since EPA’s GHGRP data are not available for 1990 through 2009, IPCC
 5 “splicing” techniques were used as per the 2006 IPCC Guidelines on time series consistency (IPCC 2006, Volume 1,
 6 Chapter 5).

7 Lime production data (by type, high-calcium- and dolomitic-quicklime, high-calcium- and dolomitic-hydrated, and
 8 dead-burned dolomite) for 1990 through 2015 (see Table 4-8) were obtained from the U.S. Geological Survey
 9 (USGS) (USGS 2016b; Corathers 2017) annual reports and are compiled by USGS to the nearest ton. Natural
 10 hydraulic lime, which is produced from CaO and hydraulic calcium silicates, is not manufactured in the United
 11 States (USGS 2011). Total lime production was adjusted to account for the water content of hydrated lime by
 12 converting hydrate to oxide equivalent based on recommendations from the IPCC, and is presented in Table 4-9
 13 (IPCC 2006). The CaO and CaO•MgO contents of lime were obtained from the IPCC (IPCC 2006). Since data for
 14 the individual lime types (high calcium and dolomitic) were not provided prior to 1997, total lime production for
 15 1990 through 1996 was calculated according to the three year distribution from 1997 to 1999.

16 **Table 4-8: High-Calcium- and Dolomitic-Quicklime, High-Calcium- and Dolomitic-Hydrated,**
 17 **and Dead-Burned-Dolomite Lime Production (kt)**

Year	High-Calcium Quicklime	Dolomitic Quicklime	High-Calcium Hydrated	Dolomitic Hydrated	Dead-Burned Dolomite
1990	11,166	2,234	1,781	319	342
2005	14,100	2,990	2,220	474	200
2011	13,900	2,690	2,010	230	200
2012	13,600	2,790	2,000	253	200
2013	13,800	2,850	2,050	260	200
2014	14,100	2,740	2,190	279	200
2015	13,100	2,550	2,150	279	200

18 **Table 4-9: Adjusted Lime Production (kt)**

Year	High-Calcium	Dolomitic
1990	12,466	2,800
2005	15,721	3,522
2011	15,367	3,051
2012	15,075	3,076
2013	15,297	3,252
2014	15,699	3,135
2015	14,670	2,945

Note: Minus water content of hydrated lime.

19 **Uncertainty and Time-Series Consistency – TO BE UPDATED**
 20 **FOR FINAL INVENTORY REPORT**

21 The uncertainties contained in these estimates can be attributed to slight differences in the chemical composition of
 22 lime products and CO₂ recovery rates for on-site process use over the time series. Although the methodology
 23 accounts for various formulations of lime, it does not account for the trace impurities found in lime, such as iron

1 oxide, alumina, and silica. Due to differences in the limestone used as a raw material, a rigid specification of lime
2 material is impossible. As a result, few plants produce lime with exactly the same properties.

3 In addition, a portion of the CO₂ emitted during lime production will actually be reabsorbed when the lime is
4 consumed, especially at captive lime production facilities. As noted above, lime has many different chemical,
5 industrial, environmental, and construction applications. In many processes, CO₂ reacts with the lime to create
6 calcium carbonate (e.g., water softening). Carbon dioxide reabsorption rates vary, however, depending on the
7 application. For example, 100 percent of the lime used to produce precipitated calcium carbonate reacts with CO₂;
8 whereas most of the lime used in steel making reacts with impurities such as silica, sulfur, and aluminum
9 compounds. Quantifying the amount of CO₂ that is reabsorbed would require a detailed accounting of lime use in the
10 United States and additional information about the associated processes where both the lime and byproduct CO₂ are
11 “reused” are required to quantify the amount of CO₂ that is reabsorbed. Research conducted thus far has not yielded
12 the necessary information to quantify CO₂ reabsorption rates.⁹ However, some additional information on the amount
13 of CO₂ consumed on site at lime facilities has been obtained from EPA’s GHGRP.

14 In some cases, lime is generated from calcium carbonate byproducts at pulp mills and water treatment plants.¹⁰ The
15 lime generated by these processes is included in the USGS data for commercial lime consumption. In the pulping
16 industry, mostly using the Kraft (sulfate) pulping process, lime is consumed in order to causticize a process liquor
17 (green liquor) composed of sodium carbonate and sodium sulfide. The green liquor results from the dilution of the
18 smelt created by combustion of the black liquor where biogenic carbon (C) is present from the wood. Kraft mills
19 recover the calcium carbonate “mud” after the causticizing operation and calcine it back into lime—thereby
20 generating CO₂—for reuse in the pulping process. Although this re-generation of lime could be considered a lime
21 manufacturing process, the CO₂ emitted during this process is mostly biogenic in origin, and therefore is not
22 included in the industrial processes totals (Miner and Upton 2002). In accordance with IPCC methodological
23 guidelines, any such emissions are calculated by accounting for net C fluxes from changes in biogenic C reservoirs
24 in wooded or crop lands (see the Land Use, Land-Use Change, and Forestry chapter).

25 In the case of water treatment plants, lime is used in the softening process. Some large water treatment plants may
26 recover their waste calcium carbonate and calcine it into quicklime for reuse in the softening process. Further
27 research is necessary to determine the degree to which lime recycling is practiced by water treatment plants in the
28 United States.

29 Another uncertainty is the assumption that calcination emissions for LKD are around 2 percent. The National Lime
30 Association (NLA) has commented that the estimates of emissions from LKD in the United States could be closer to
31 6 percent. They also note that additional emissions (approximately 2 percent) may also be generated through
32 production of other byproducts/wastes (off-spec lime that is not recycled, scrubber sludge) at lime plants (Seeger
33 2013). There is limited data publicly available on LKD generation rates and also quantities, types of other
34 byproducts/wastes produced at lime facilities. Further research and data is needed to improve understanding of
35 additional calcination emissions to consider revising the current assumptions that are based on IPCC guidelines. In
36 preparing estimates for the current inventory, EPA initiated a dialogue with NLA to discuss data needs to generate a
37 country specific LKD factor and is reviewing the information provided by NLA. More information can be found in
38 the Planned Improvements section below.

39 The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-10. Lime CO₂ emissions
40 for 2015 were estimated to be between 13.8 and 14.5 MMT CO₂ Eq. at the 95 percent confidence level. This
41 confidence level indicates a range of approximately 3 percent below and 3 percent above the emission estimate of
42 14.1 MMT CO₂ Eq.

⁹ Representatives of the National Lime Association estimate that CO₂ reabsorption that occurs from the use of lime may offset as much as a quarter of the CO₂ emissions from calcination (Males 2003).

¹⁰ Some carbide producers may also regenerate lime from their calcium hydroxide byproducts, which does not result in emissions of CO₂. In making calcium carbide, quicklime is mixed with coke and heated in electric furnaces. The regeneration of lime in this process is done using a waste calcium hydroxide (hydrated lime) [CaC₂ + 2H₂O → C₂H₂ + Ca(OH)₂], not calcium carbonate [CaCO₃]. Thus, the calcium hydroxide is heated in the kiln to simply expel the water [Ca(OH)₂ + heat → CaO + H₂O] and no CO₂ is released.

Table 4-10: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Lime Production (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Lime Production	CO ₂	14.1	13.8	14.5	-3%	+3%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Recalculations Discussion

Updated data from Lisa Corathers (U.S. Geological Survey) (Corathers 2017) resulted in High-Calcium Quicklime production data changes for 2014 and Dolomitic Quicklime production data changes for 2013 and 2014, as shown in Table 4-8.

Recovered emissions shown in Table 4-7 were updated using aggregated GHGRP data from 2010 to 2015. This data changed slightly from previous Inventory reports due to the adoption of new rounding technique to maintain consistency with other data sets. Both of these data updates resulted in changes to emissions estimates across the time-series (2011 to 2015) of less than 1 percent.

Planned Improvements

Future improvements involve finishing review of data to improve current assumptions associated with emissions from production of LKD and other byproducts/wastes as discussed in the Uncertainty and Time-Series Consistency section per comments from the NLA provided during the public review of the draft 2015 Inventory. In response to comments, EPA met with NLA on April 7, 2015 to outline specific information required to apply IPCC methods to develop a country-specific correction factor to more accurately estimate emissions from production of LKD. In response to this technical meeting, in January and February 2016, NLA compiled and shared historical emissions information reported by member facilities on an annual basis under voluntary reporting initiatives over 2002 through 2011 associated with generation of total calcined byproducts and LKD (LKD reporting only differentiated starting in 2010). This emissions information was reported on a voluntary basis consistent with NLA's facility-level reporting protocol also recently provided. EPA has reviewed the information provided by NLA and plans to work with them to address need for EPA's analysis, as there is limited information across the time series. Due to limited resources and need for additional QA of information, this planned improvement is still in process and has not been incorporated into this current Inventory report. As an interim step, EPA plans to update the qualitative description of uncertainty to reflect the information provided by NLA in the final report.

In addition, EPA plans to also review GHGRP emissions and activity data reported to EPA under Subpart S, in particular review of aggregated activity data on lime production, by type. Particular attention will be made to also ensuring time series consistency of the emissions estimates presented in future Inventory reports, consistent with IPCC and UNFCCC guidelines. This is required as the facility-level reporting data from EPA's GHGRP, with the program's initial requirements for reporting of emissions in calendar year 2010, are not available for all inventory years (i.e., 1990 through 2009) as required for this Inventory. In implementing improvements and integration of data from EPA's GHGRP, the latest guidance from the IPCC on the use of facility-level data in national inventories will be relied upon.¹¹

¹¹ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

4.3 Glass Production (IPCC Source Category 2A3)

Glass production is an energy and raw-material intensive process that results in the generation of CO₂ from both the energy consumed in making glass and the glass process itself. Emissions from fuels consumed for energy purposes during the production of glass are accounted for in the Energy sector.

Glass production employs a variety of raw materials in a glass-batch. These include formers, fluxes, stabilizers, and sometimes colorants. The major raw materials (i.e., fluxes and stabilizers) which emit process-related carbon dioxide (CO₂) emissions during the glass melting process are limestone, dolomite, and soda ash. The main former in all types of glass is silica (SiO₂). Other major formers in glass include feldspar and boric acid (i.e., borax). Fluxes are added to lower the temperature at which the batch melts. Most commonly used flux materials are soda ash (sodium carbonate, Na₂CO₃) and potash (potassium carbonate, K₂O). Stabilizers are used to make glass more chemically stable and to keep the finished glass from dissolving and/or falling apart. Commonly used stabilizing agents in glass production are limestone (CaCO₃), dolomite (CaCO₃MgCO₃), alumina (Al₂O₃), magnesia (MgO), barium carbonate (BaCO₃), strontium carbonate (SrCO₃), lithium carbonate (Li₂CO₃), and zirconia (ZrO₂) (OIT 2002). Glass makers also use a certain amount of recycled scrap glass (cullet), which comes from in-house return of glassware broken in the process or other glass spillage or retention such as recycling or cullet broker services.

The raw materials (primarily limestone, dolomite and soda ash) release CO₂ emissions in a complex high-temperature chemical reaction during the glass melting process. This process is not directly comparable to the calcination process used in lime manufacturing, cement manufacturing, and process uses of carbonates (i.e., limestone/dolomite use), but has the same net effect in terms of CO₂ emissions (IPCC 2006). The U.S. glass industry can be divided into four main categories: containers, flat (window) glass, fiber glass, and specialty glass. The majority of commercial glass produced is container and flat glass (EPA 2009). The United States is one of the major global exporters of glass. Domestically, demand comes mainly from the construction, auto, bottling, and container industries. There are over 1,500 companies that manufacture glass in the United States, with the largest being Corning, Guardian Industries, Owens-Illinois, and PPG Industries.¹²

In 2015, 341 kilotons of limestone and 2,390 kilotons of soda ash were consumed for glass production (USGS 2015c; Willett 2017). Dolomite consumption data for glass manufacturing was reported to be zero for 2015. Use of limestone and soda ash in glass production resulted in aggregate CO₂ emissions of 1.3 MMT CO₂ Eq. (1,299 kt) (see Table 4-11). Overall, emissions have decreased 15 percent from 1990 through 2015.

Emissions in 2015 decreased approximately 3 percent from 2014 levels while, in general, emissions from glass production have remained relatively constant over the time series with some fluctuations since 1990. In general, these fluctuations were related to the behavior of the export market and the U.S. economy. Specifically, the extended downturn in residential and commercial construction and automotive industries between 2008 and 2010 resulted in reduced consumption of glass products, causing a drop in global demand for limestone/dolomite and soda ash, and a corresponding decrease in emissions. Furthermore, the glass container sector is one of the leading soda ash consuming sectors in the United States. Some commercial food and beverage package manufacturers are shifting from glass containers towards lighter and more cost effective polyethylene terephthalate (PET) based containers, putting downward pressure on domestic consumption of soda ash (USGS 1995 through 2015c).

Table 4-11: CO₂ Emissions from Glass Production (MMT CO₂ Eq. and kt)

Year	MMT CO ₂ Eq.	kt
1990	1.5	1,535
2005	1.9	1,928

2012	1.2	1,248
2013	1.3	1,317
2014	1.3	1,336
2015	1.3	1,299

Note: Totals may not sum due to independent rounding

1 Methodology

2 Carbon dioxide emissions were calculated based on the 2006 IPCC Guidelines Tier 3 method by multiplying the
3 quantity of input carbonates (limestone, dolomite, and soda ash) by the carbonate-based emission factor (in metric
4 tons CO₂/metric ton carbonate): limestone, 0.43971; dolomite, 0.47732; and soda ash, 0.41492.

5 Consumption data for 1990 through 2015 of limestone, dolomite, and soda ash used for glass manufacturing were
6 obtained from the U.S. Geological Survey (USGS) *Minerals Yearbook: Crushed Stone Annual Report* (1995 through
7 2015b), 2015 preliminary data from the USGS Crushed Stone Commodity Expert (Willett 2017), the *USGS*
8 *Minerals Yearbook: Soda Ash Annual Report* (1995 through 2015) (USGS 1995 through 2015c), USGS Mineral
9 Industry Surveys for Soda Ash in January 2015 (USGS 2015a) and the U.S. Bureau of Mines (1991 and 1993a),
10 which are reported to the nearest ton. During 1990 and 1992, the USGS did not conduct a detailed survey of
11 limestone and dolomite consumption by end-use. Consumption for 1990 was estimated by applying the 1991
12 percentages of total limestone and dolomite use constituted by the individual limestone and dolomite uses to 1990
13 total use. Similarly, the 1992 consumption figures were approximated by applying an average of the 1991 and 1993
14 percentages of total limestone and dolomite use constituted by the individual limestone and dolomite uses to the
15 1992 total.

16 Additionally, each year the USGS withholds data on certain limestone and dolomite end-uses due to confidentiality
17 agreements regarding company proprietary data. For the purposes of this analysis, emissive end-uses that contained
18 withheld data were estimated using one of the following techniques: (1) the value for all the withheld data points for
19 limestone or dolomite use was distributed evenly to all withheld end-uses; or (2) the average percent of total
20 limestone or dolomite for the withheld end-use in the preceding and succeeding years.

21 There is a large quantity of limestone and dolomite reported to the USGS under the categories “unspecified–
22 reported” and “unspecified–estimated.” A portion of this consumption is believed to be limestone or dolomite used
23 for glass manufacturing. The quantities listed under the “unspecified” categories were, therefore, allocated to glass
24 manufacturing according to the percent limestone or dolomite consumption for glass manufacturing end use for that
25 year.¹³

26 Based on the 2015 reported data, the estimated distribution of soda ash consumption for glass production compared
27 to total domestic soda ash consumption is 48 percent (USGS 1995 through 2015c).

28 **Table 4-12: Limestone, Dolomite, and Soda Ash Consumption Used in Glass Production (kt)**

Activity	1990	2005	2011	2012	2013	2014	2015
Limestone	430	920	614	555	693	775	341
Dolomite	59	541	0	0	0	0	0
Soda Ash	3,177	3,050	2,480	2,420	2,440	2,410	2,390
Total	3,666	4,511	3,094	2,975	3,133	3,185	2,731

¹³ This approach was recommended by USGS.

Uncertainty and Time-Series Consistency – TO BE UPDATED FOR FINAL INVENTORY REPORT

The uncertainty levels presented in this section arise in part due to variations in the chemical composition of limestone used in glass production. In addition to calcium carbonate, limestone may contain smaller amounts of magnesia, silica, and sulfur, among other minerals (potassium carbonate, strontium carbonate and barium carbonate, and dead burned dolomite). Similarly, the quality of the limestone (and mix of carbonates) used for glass manufacturing will depend on the type of glass being manufactured.

The estimates below also account for uncertainty associated with activity data. Large fluctuations in reported consumption exist, reflecting year-to-year changes in the number of survey responders. The uncertainty resulting from a shifting survey population is exacerbated by the gaps in the time series of reports. The accuracy of distribution by end use is also uncertain because this value is reported by the manufacturer of the input carbonates (limestone, dolomite & soda ash) and not the end user. For 2015, there has been no reported consumption of dolomite for glass manufacturing. This data has been reported to USGS by dolomite manufacturers and not end-users (i.e., glass manufacturers). There is a high uncertainty associated with this estimate, as dolomite is a major raw material consumed in glass production. Additionally, there is significant inherent uncertainty associated with estimating withheld data points for specific end uses of limestone and dolomite. The uncertainty of the estimates for limestone and dolomite used in glass making is especially high. Lastly, much of the limestone consumed in the United States is reported as “other unspecified uses;” therefore, it is difficult to accurately allocate this unspecified quantity to the correct end-uses. Further research is needed into alternate and more complete sources of data on carbonate-based raw material consumption by the glass industry.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-13. In 2015, glass production CO₂ emissions were estimated to be between 1.3 and 1.4 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 4 percent below and 5 percent above the emission estimate of 1.3 MMT CO₂ Eq.

Table 4-13: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Glass Production (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a (%)			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Glass Production	CO ₂	1.3	1.3	1.4	-4%	+5%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Recalculations Discussion

Limestone and dolomite consumption data for 2014 was revised relative to the previous Inventory based on the preliminary data obtained directly from the USGS Crush Stone Commodity expert, Jason Willett (Willett 2017). In the previous Inventory (i.e., 1990 through 2014), preliminary data were used for 2014 and updated for the current Inventory. The published time series was reviewed to ensure time series consistency. This update caused a decrease in 2014 emissions of less than 1 percent compared to 2014 emissions from the previous inventory (i.e., 1990 through 2014).

Planned Improvements

As noted in the prior reports, current publicly available activity data shows consumption of only limestone and soda ash for glass manufacturing. While limestone and soda ash are the predominant carbonates used in glass

1 manufacturing, there are other carbonates that are also consumed for glass manufacturing, although in smaller
2 quantities. EPA has initiated review of activity data on carbonate consumption, by type by the glass industry from
3 EPA's Greenhouse Gas Reporting Program (GHGRP) reported annually since 2010.

4 EPA has initiated review of this activity data and is hopes to finalize assessment for future integration of data
5 reported under EPA's GHGRP this spring to improve the completeness of emission estimates and facilitate
6 category-specific QC for the Glass Production source category. EPA's GHGRP has an emission threshold for
7 reporting, so the assessment will consider the completeness of carbonate consumption data for glass production in
8 the United States. Particular attention will also be made to also ensuring time series consistency of the emissions
9 estimates presented in future Inventory reports, consistent with IPCC and UNFCCC guidelines. This is required as
10 the facility-level reporting data from EPA's GHGRP, with the program's initial requirements for reporting of
11 emissions in calendar year 2010, are not available for all inventory years (i.e., 1990 through 2009) as required for
12 this Inventory. In implementing improvements and integration of data from EPA's GHGRP, the latest guidance
13 from the IPCC on the use of facility-level data in national inventories will be relied upon.¹⁴ These planned
14 improvements are ongoing and EPA hopes to also initiate research into other sources of activity data for carbonate
15 consumption by the glass industry.

16 4.4 Other Process Uses of Carbonates (IPCC 17 Source Category 2A4)

18 Limestone (CaCO_3), dolomite ($\text{CaCO}_3\text{MgCO}_3$),¹⁵ and other carbonates such as soda ash, magnesite, and siderite are
19 basic materials used by a wide variety of industries, including construction, agriculture, chemical, metallurgy, glass
20 production, and environmental pollution control. This section addresses only limestone and dolomite use. For
21 industrial applications, carbonates such as limestone and dolomite are heated sufficiently enough to calcine the
22 material and generate CO_2 as a byproduct.

25 Examples of such applications include limestone used as a flux or purifier in metallurgical furnaces, as a sorbent in
26 flue gas desulfurization (FGD) systems for utility and industrial plants, and as a raw material for the production of
27 glass, lime, and cement. Emissions from limestone and dolomite used in other process sectors such as cement, lime,
28 glass production, and iron and steel, are excluded from this section and reported under their respective source
29 categories (e.g., Section 4.3, Glass Production). Emission from soda ash consumption is reported under respective
30 categories (e.g., Glass Manufacturing (IPCC Source Category 2A3) and Soda Ash Production and Consumption
31 (IPCC Source Category 2B7)). Emissions from fuels consumed for energy purposes during these processes are
32 accounted for in the Energy chapter.

33 Limestone is widely distributed throughout the world in deposits of varying sizes and degrees of purity. Large
34 deposits of limestone occur in nearly every state in the United States, and significant quantities are extracted for
35 industrial applications. In 2014, the leading limestone producing states are Texas, Missouri, Florida, Ohio, and
36 Kentucky, which contribute 43 percent of the total U.S. output (USGS 1995a through 2015). Similarly, dolomite
37 deposits are also widespread throughout the world. Dolomite deposits are found in the United States, Canada, Mexico,
38 Europe, Africa, and Brazil. In the United States, the leading dolomite producing states are Illinois, Pennsylvania, and
39 New York, which contribute 55 percent of the total 2014 U.S. output (USGS 1995a through 2015).

40 In 2015, 22,322 kt of limestone and 3,244 kt of dolomite were consumed for these emissive applications, excluding
41 glass manufacturing (Willett 2017). Usage of limestone and dolomite resulted in aggregate CO_2 emissions of 10.8

¹⁴ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

¹⁵ Limestone and dolomite are collectively referred to as limestone by the industry, and intermediate varieties are seldom distinguished.

1 MMT CO₂ Eq. (10,828 kt) (see Table 4-14 and Table 4-15). While 2015 emissions have decreased 8 percent
 2 compared to 2014, overall emissions have increased 121 percent from 1990 through 2015.

3 **Table 4-14: CO₂ Emissions from Other Process Uses of Carbonates (MMT CO₂ Eq.)**

Year	Flux Stone	FGD	Magnesium Production	Other Miscellaneous Uses ^a	Total
1990	2.6	1.4	0.1	0.8	4.9
2005	2.6	3.0	0.0	0.7	6.3
2011	1.5	5.4	0.0	2.4	9.3
2012	1.1	5.8	0.0	1.1	8.0
2013	2.3	6.3	0.0	1.8	10.4
2014	2.9	7.1	0.0	1.8	11.8
2015	3.0	7.3	0.0	0.5	10.8

^a “Other miscellaneous uses” include chemical stone, mine dusting or acid water treatment, acid neutralization, and sugar refining.

Note: Totals may not sum due to independent rounding.

4 **Table 4-15: CO₂ Emissions from Other Process Uses of Carbonates (kt)**

Year	Flux Stone	FGD	Magnesium Production	Other Miscellaneous Uses ^a	Total
1990	2,592	1,432	64	819	4,907
2005	2,649	2,973	0	718	6,339
2011	1,467	5,420	0	2,449	9,335
2012	1,077	5,797	0	1,148	8,022
2013	2,307	6,309	0	1,798	10,414
2014	2,911	7,111	0	1,790	11,811
2015	3,031	7,335	0	462	10,828

^a “Other miscellaneous uses” include chemical stone, mine dusting or acid water treatment, acid neutralization, and sugar refining.

Note: Totals may not sum due to independent rounding.

5 Methodology

6 Carbon dioxide emissions were calculated based on the *2006 IPCC Guidelines* Tier 2 method by multiplying the
 7 quantity of limestone or dolomite consumed by the emission factor for limestone or dolomite calcination,
 8 respectively, Table 2.1–limestone: 0.43971 metric ton CO₂/metric ton carbonate, and dolomite: 0.47732 metric ton
 9 CO₂/metric ton carbonate.¹⁶ This methodology was used for flux stone, flue gas desulfurization systems, chemical
 10 stone, mine dusting or acid water treatment, acid neutralization, and sugar refining. Flux stone used during the
 11 production of iron and steel was deducted from the Other Process Uses of Carbonates source category estimate and
 12 attributed to the Iron and Steel Production source category estimate. Similarly, limestone and dolomite consumption
 13 for glass manufacturing, cement, and lime manufacturing are excluded from this category and attributed to their
 14 respective categories.

15 Historically, the production of magnesium metal was the only other significant use of limestone and dolomite that
 16 produced CO₂ emissions. At the end of 2001, the sole magnesium production plant operating in the United States

¹⁶ *2006 IPCC Guidelines*, Volume 3: Chapter 2.

1 that produced magnesium metal using a dolomitic process that resulted in the release of CO₂ emissions ceased its
 2 operations (USGS 1995b through 2012; USGS 2013).

3 Consumption data for 1990 through 2015 of limestone and dolomite used for flux stone, flue gas desulfurization
 4 systems, chemical stone, mine dusting or acid water treatment, acid neutralization, and sugar refining (see Table
 5 4-16) were obtained from the U.S. Geological Survey (USGS) *Minerals Yearbook: Crushed Stone Annual Report*
 6 (1995a through 2015), preliminary data for 2015 from USGS Crushed Stone Commodity Expert (Willett 2017),
 7 American Iron and Steel Institute limestone and dolomite consumption data (AISI 2016), and the U.S. Bureau of
 8 Mines (1991 and 1993a), which are reported to the nearest ton. The production capacity data for 1990 through 2015
 9 of dolomitic magnesium metal also came from the USGS (1995b through 2012; USGS 2013) and the U.S. Bureau of
 10 Mines (1990 through 1993b). During 1990 and 1992, the USGS did not conduct a detailed survey of limestone and
 11 dolomite consumption by end-use. Consumption for 1990 was estimated by applying the 1991 percentages of total
 12 limestone and dolomite use constituted by the individual limestone and dolomite uses to 1990 total use. Similarly,
 13 the 1992 consumption figures were approximated by applying an average of the 1991 and 1993 percentages of total
 14 limestone and dolomite use constituted by the individual limestone and dolomite uses to the 1992 total.

15 Additionally, each year the USGS withholds data on certain limestone and dolomite end-uses due to confidentiality
 16 agreements regarding company proprietary data. For the purposes of this analysis, emissive end-uses that contained
 17 withheld data were estimated using one of the following techniques: (1) the value for all the withheld data points for
 18 limestone or dolomite use was distributed evenly to all withheld end-uses; (2) the average percent of total limestone
 19 or dolomite for the withheld end-use in the preceding and succeeding years; or (3) the average fraction of total
 20 limestone or dolomite for the end-use over the entire time period.

21 There is a large quantity of crushed stone reported to the USGS under the category “unspecified uses.” A portion of
 22 this consumption is believed to be limestone or dolomite used for emissive end uses. The quantity listed for
 23 “unspecified uses” was, therefore, allocated to each reported end-use according to each end-use’s fraction of total
 24 consumption in that year.¹⁷

25 **Table 4-16: Limestone and Dolomite Consumption (kt)**

Activity	1990	2005	2011	2012	2013	2014	2015
Flux Stone	6,737	7,022	4,396	3,666	6,345	7,599	7,834
Limestone	5,804	3,165	2,531	3,108	4,380	4,243	4,590
Dolomite	933	3,857	1,865	559	1,965	3,356	3,244
FGD	3,258	6,761	12,326	13,185	14,347	16,171	16,680
Other Miscellaneous Uses	1,835	1,632	5,548	2,610	3,973	4,069	1,052
Total	11,830	15,415	22,270	19,461	24,665	27,839	25,566

26 **Uncertainty and Time-Series Consistency – TO BE UPDATED**
 27 **FOR FINAL INVENTORY REPORT**

28 The uncertainty levels presented in this section account for uncertainty associated with activity data. Data on
 29 limestone and dolomite consumption are collected by USGS through voluntary national surveys. USGS contacts the
 30 mines (i.e., producers of various types of crushed stone) for annual sales data. Data on other carbonate consumption
 31 are not readily available. The producers report the annual quantity sold to various end-users/industry types. USGS
 32 estimates the historical response rate for the crushed stone survey to be approximately 70 percent, the rest is
 33 estimated by USGS. Large fluctuations in reported consumption exist, reflecting year-to-year changes in the number
 34 of survey responders. The uncertainty resulting from a shifting survey population is exacerbated by the gaps in the
 35 time series of reports. The accuracy of distribution by end use is also uncertain because this value is reported by the
 36 producer/mines and not the end user. Additionally, there is significant inherent uncertainty associated with
 37 estimating withheld data points for specific end uses of limestone and dolomite. Lastly, much of the limestone

¹⁷ This approach was recommended by USGS, the data collection agency.

consumed in the United States is reported as “other unspecified uses;” therefore, it is difficult to accurately allocate this unspecified quantity to the correct end-uses.

Uncertainty in the estimates also arises in part due to variations in the chemical composition of limestone. In addition to calcium carbonate, limestone may contain smaller amounts of magnesia, silica, and sulfur, among other minerals. The exact specifications for limestone or dolomite used as flux stone vary with the pyrometallurgical process and the kind of ore processed.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-17. Carbon dioxide emissions from other process uses of carbonates in 2015 were estimated to be between 10.7 and 14.0 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 12 percent below and 15 percent above the emission estimate of 12.1 MMT CO₂ Eq.

Table 4-17: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Other Process Uses of Carbonates (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Other Process Uses of Carbonates	CO ₂	12.1	10.7	14.0	-12%	+15%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Recalculations Discussion

Limestone and dolomite consumption data, by end-use, for 2014 was updated relative to the previous Inventory based on the preliminary data provided by USGS Crush Stone Commodity expert, Jason Willett. In the previous Inventory (i.e., 1990 through 2014), preliminary data were used for 2014 and updated for the current Inventory. The published time series was reviewed to ensure time series consistency. This update caused a decrease in total limestone and dolomite consumption for emissive end uses in 2014 by approximately 2 percent.

Planned Improvements

Pending available resources, this section will integrate and present emissions from soda ash consumption for other chemical uses (non-glass production). Currently, in this document, these estimates are presented along with emissions from soda ash production (IPCC Category 2B7). This improvement is planned for the final version of this year’s inventory report and is not incorporated into this public review draft.

4.5 Ammonia Production (IPCC Source Category 2B1)

Emissions of carbon dioxide (CO₂) occur during the production of synthetic ammonia, primarily through the use of natural gas, petroleum coke, or naphtha as a feedstock. The natural gas-, naphtha-, and petroleum coke-based processes produce CO₂ and hydrogen (H₂), the latter of which is used in the production of ammonia. The brine electrolysis process for production of ammonia does not lead to process-based CO₂ emissions. Emissions from fuels consumed for energy purposes during the production of ammonia are accounted for in the Energy chapter.

1 In the United States, the majority of ammonia is produced using a natural gas feedstock; however, one synthetic
 2 ammonia production plant located in Kansas is producing ammonia from petroleum coke feedstock. In some U.S.
 3 plants, some of the CO₂ produced by the process is captured and used to produce urea rather than being emitted to
 4 the atmosphere. There are approximately 13 companies operating 26 ammonia producing facilities in 17 states.
 5 More than 55 percent of domestic ammonia production capacity is concentrated in the states of Louisiana (29
 6 percent), Oklahoma (20 percent), and Texas (6 percent) (USGS 2016).

7 There are five principal process steps in synthetic ammonia production from natural gas feedstock. The primary
 8 reforming step converts methane (CH₄) to CO₂, carbon monoxide (CO), and H₂ in the presence of a catalyst. Only
 9 30 to 40 percent of the CH₄ feedstock to the primary reformer is converted to CO and CO₂ in this step of the
 10 process. The secondary reforming step converts the remaining CH₄ feedstock to CO and CO₂. The CO in the process
 11 gas from the secondary reforming step (representing approximately 15 percent of the process gas) is converted to
 12 CO₂ in the presence of a catalyst, water, and air in the shift conversion step. Carbon dioxide is removed from the
 13 process gas by the shift conversion process, and the hydrogen gas is combined with the nitrogen (N₂) gas in the
 14 process gas during the ammonia synthesis step to produce ammonia. The CO₂ is included in a waste gas stream with
 15 other process impurities and is absorbed by a scrubber solution. In regenerating the scrubber solution, CO₂ is
 16 released from the solution.

17 The conversion process for conventional steam reforming of CH₄, including the primary and secondary reforming
 18 and the shift conversion processes, is approximately as follows:

21 To produce synthetic ammonia from petroleum coke, the petroleum coke is gasified and converted to CO₂ and H₂.
 22 These gases are separated, and the H₂ is used as a feedstock to the ammonia production process, where it is reacted
 23 with N₂ to form ammonia.

24 Not all of the CO₂ produced during the production of ammonia is emitted directly to the atmosphere. Some of the
 25 ammonia and some of the CO₂ produced by the synthetic ammonia process are used as raw materials in the
 26 production of urea [CO(NH₂)₂], which has a variety of agricultural and industrial applications.

27 The chemical reaction that produces urea is:

29 Only the CO₂ emitted directly to the atmosphere from the synthetic ammonia production process is accounted for in
 30 determining emissions from ammonia production. The CO₂ that is captured during the ammonia production process
 31 and used to produce urea does not contribute to the CO₂ emission estimates for ammonia production presented in
 32 this section. Instead, CO₂ emissions resulting from the consumption of urea are attributed to the urea consumption or
 33 urea application source category (under the assumption that the carbon stored in the urea during its manufacture is
 34 released into the environment during its consumption or application). Emissions of CO₂ resulting from agricultural
 35 applications of urea are accounted for in the Agriculture chapter. Previously, these emission estimates from the
 36 agricultural application of urea were accounted for in the *Cropland Remaining Cropland* section of the Land Use,
 37 Land Use Change, and Forestry chapter. Emissions of CO₂ resulting from non-agricultural applications of urea (e.g.,
 38 use as a feedstock in chemical production processes) are accounted for in the Urea Consumption for Non-
 39 Agricultural Purposes section of this chapter.

40 Total emissions of CO₂ from ammonia production in 2015 were 10.8 MMT CO₂ Eq. (10,799 kt), and are
 41 summarized in Table 4-18 and Table 4-19. Ammonia production relies on natural gas as both a feedstock and a fuel,
 42 and as such, market fluctuations and volatility in natural gas prices affect the production of ammonia. Since 1990,
 43 emissions from ammonia production have decreased by 17 percent. Emissions in 2015 have increased by
 44 approximately 12 percent from the 2014 levels.

45 **Table 4-18: CO₂ Emissions from Ammonia Production (MMT CO₂ Eq.)**

Source	1990	2005	2011	2012	2013	2014	2015
Ammonia Production	13.0	9.2	9.3	9.4	10.0	9.6	10.8
Total	13.0	9.2	9.3	9.4	10.0	9.6	10.8

1 **Table 4-19: CO₂ Emissions from Ammonia Production (kt)**

Source	1990	2005	2011	2012	2013	2014	2015
Ammonia Production	13,047	9,196	9,292	9,377	9,962	9,619	10,799
Total	13,047	9,196	9,292	9,377	9,962	9,619	10,799

2 **Methodology**

3 Carbon dioxide emissions from production of synthetic ammonia from natural gas feedstock is based on the 2006
 4 *IPCC Guidelines* (IPCC 2006) Tier 1 and 2 method. A country-specific emission factor is developed and applied to
 5 national ammonia production to estimate emissions. The method uses a CO₂ emission factor published by the
 6 European Fertilizer Manufacturers Association (EFMA) that is based on natural gas-based ammonia production
 7 technologies that are similar to those employed in the United States. This CO₂ emission factor of 1.2 metric tons
 8 CO₂/metric ton NH₃ (EFMA 2000a) is applied to the percent of total annual domestic ammonia production from
 9 natural gas feedstock.

10 Emissions of CO₂ from ammonia production are then adjusted to account for the use of some of the CO₂ produced
 11 from ammonia production as a raw material in the production of urea. The CO₂ emissions reported for ammonia
 12 production are reduced by a factor of 0.733 multiplied by total annual domestic urea production. This corresponds to
 13 a stoichiometric CO₂/urea factor of 44/60, assuming complete conversion of ammonia (NH₃) and CO₂ to urea (IPCC
 14 2006; EFMA 2000b).

15 All synthetic ammonia production and subsequent urea production are assumed to be from the same process—
 16 conventional catalytic reforming of natural gas feedstock, with the exception of ammonia production from
 17 petroleum coke feedstock at one plant located in Kansas. Annual ammonia and urea production are shown in Table
 18 4-20. The CO₂ emission factor for production of ammonia from petroleum coke is based on plant-specific data,
 19 wherein all carbon contained in the petroleum coke feedstock that is not used for urea production is assumed to be
 20 emitted to the atmosphere as CO₂ (Bark 2004). Ammonia and urea are assumed to be manufactured in the same
 21 manufacturing complex, as both the raw materials needed for urea production are produced by the ammonia
 22 production process. The CO₂ emission factor of 3.57 metric tons CO₂/metric ton NH₃ for the petroleum coke
 23 feedstock process (Bark 2004) is applied to the percent of total annual domestic ammonia production from
 24 petroleum coke feedstock.

25 The emission factor of 1.2 metric ton CO₂/metric ton NH₃ for production of ammonia from natural gas feedstock
 26 was taken from the EFMA Best Available Techniques publication, *Production of Ammonia* (EFMA 2000a). The
 27 EFMA reported an emission factor range of 1.15 to 1.30 metric ton CO₂/metric ton NH₃, with 1.2 metric ton
 28 CO₂/metric ton NH₃ as a typical value (EFMA 2000a). Technologies (e.g., catalytic reforming process, etc.)
 29 associated with this factor are found to closely resemble those employed in the United States for use of natural gas
 30 as a feedstock. The EFMA reference also indicates that more than 99 percent of the CH₄ feedstock to the catalytic
 31 reforming process is ultimately converted to CO₂. As noted earlier, emissions from fuels consumed for energy
 32 purposes during the production of ammonia are accounted for in the Energy chapter. The total ammonia production
 33 data for 2011 through 2015 were obtained from American Chemistry Council (2016). For years before 2011,
 34 ammonia production data (see Table 4-20) were obtained from Coffeyville Resources (Coffeyville 2005, 2006,
 35 2007a, 2007b, 2009, 2010, 2011, and 2012) and the Census Bureau of the U.S. Department of Commerce (U.S.
 36 Census Bureau 1991 through 1994, 1998 through 2011) as reported in *Current Industrial Reports Fertilizer Materials*
 37 *and Related Products* annual and quarterly reports. Urea-ammonia nitrate production from petroleum coke for years
 38 through 2011 was obtained from Coffeyville Resources (Coffeyville 2005, 2006, 2007a, 2007b, 2009, 2010, 2011,
 39 and 2012), and from CVR Energy, Inc. Annual Report (CVR 2012, 2014, 2015, and 2016) for 2012, 2013, 2014,
 40 and 2015. Urea production data for 1990 through 2008 were obtained from the *Minerals Yearbook: Nitrogen* (USGS
 41 1994 through 2009). Urea production data for 2009 through 2010 were obtained from the U.S. Census Bureau (U.S.
 42 Census Bureau 2010 and 2011). The U.S. Census Bureau ceased collection of urea production statistics, and urea
 43 production data for 2011, 2012, 2013 and 2014 were obtained from the *Minerals Yearbook: Nitrogen* (USGS 2015,
 44 2016). USGS urea production data for 2015 was not yet published and so 2014 data were used as a proxy for 2015.

1 **Table 4-20: Ammonia Production and Urea Production (kt)**

Year	Ammonia Production	Urea Production
1990	15,425	7,450
2005	10,143	5,270
2011	10,325	5,430
2012	10,305	5,220
2013	10,930	5,480
2014	10,515	5,230
2015	11,505	5,230

2 **Uncertainty and Time-Series Consistency – TO BE UPDATED**
 3 **FOR FINAL INVENTORY REPORT**

4 The uncertainties presented in this section are primarily due to how accurately the emission factor used represents an
 5 average across all ammonia plants using natural gas feedstock. Uncertainties are also associated with ammonia
 6 production estimates and the assumption that all ammonia production and subsequent urea production was from the
 7 same process—conventional catalytic reforming of natural gas feedstock, with the exception of one ammonia
 8 production plant located in Kansas that is manufacturing ammonia from petroleum coke feedstock. Uncertainty is
 9 also associated with the representativeness of the emission factor used for the petroleum coke-based ammonia
 10 process. It is also assumed that ammonia and urea are produced at collocated plants from the same natural gas raw
 11 material.

12 Recovery of CO₂ from ammonia production plants for purposes other than urea production (e.g., commercial sale,
 13 etc.) has not been considered in estimating the CO₂ emissions from ammonia production, as data concerning the
 14 disposition of recovered CO₂ are not available. Such recovery may or may not affect the overall estimate of CO₂
 15 emissions depending upon the end use to which the recovered CO₂ is applied. Further research is required to
 16 determine whether byproduct CO₂ is being recovered from other ammonia production plants for application to end
 17 uses that are not accounted for elsewhere.

18 The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-21. Carbon dioxide
 19 emissions from ammonia production in 2015 were estimated to be between 8.7 and 10.2 MMT CO₂ Eq. at the 95
 20 percent confidence level. This indicates a range of approximately 8 percent below and 8 percent above the emission
 21 estimate of 9.4 MMT CO₂ Eq.

22 **Table 4-21: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from**
 23 **Ammonia Production (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a (MMT CO ₂ Eq.)			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Ammonia Production	CO ₂	9.4	8.7	10.2	-8%	+8%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

24 Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990
 25 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 26 above.

1 Recalculations Discussion

2 Production estimates for urea production for 2014 were updated relative to the previous Inventory using information
3 obtained from the recent 2014 *Minerals Yearbook: Nitrogen* (USGS 2016). For the previous version of the Inventory
4 (i.e., 1990 through 2014), 2013 data was used as a proxy for 2014 as the 2014 data were not published prior to the
5 previous Inventory report. This update resulted in a slight increase of emissions by approximately 2 percent for 2014
6 relative to the previous Inventory.

7 Planned Improvements

8 Future improvements involve continuing to evaluate and analyze data reported under EPA's GHGRP to improve the
9 emission estimates for the Ammonia Production source category, in particular new data from updated reporting
10 requirements finalized in October of 2014 (79 FR 63750) and December 2016 (81 FR 89188)¹⁸, that include facility-
11 level ammonia production data, will be included in future reports if the data meets GHGRP CBI aggregation criteria.
12 Particular attention will be made to ensure time series consistency of the emissions estimates presented in future
13 Inventory reports, along with application of appropriate category-specific QC procedures consistent with IPCC and
14 UNFCCC guidelines. This is required as the facility-level reporting data from EPA's GHGRP, with the program's
15 initial requirements for reporting of emissions in calendar year 2010, are not available for all inventory years (i.e.,
16 1990 through 2009) as required for this Inventory. In implementing improvements and integration of data from
17 EPA's GHGRP, the latest guidance from the IPCC on the use of facility-level data in national inventories will be
18 relied upon.¹⁹ Specifically, the planned improvements include assessing data to update the emission factors to
19 include both fuel and feedstock CO₂ emissions and incorporate CO₂ capture and storage. Methodologies will also be
20 updated if additional ammonia production plants are found to use hydrocarbons other than natural gas for ammonia
21 production. Due to limited resources, this planned improvement is still in development and so is not incorporated
22 into this Inventory.

23 4.6 Urea Consumption for Non-Agricultural 24 Purposes

25 Urea is produced using ammonia and carbon dioxide (CO₂) as raw materials. All urea produced in the United States
26 is assumed to be produced at ammonia production facilities where both ammonia and CO₂ are generated. There are
27 approximately 20 of these facilities operating in the United States.

28 The chemical reaction that produces urea is:

30 This section accounts for CO₂ emissions associated with urea consumed exclusively for non-agricultural purposes.
31 Carbon dioxide emissions associated with urea consumed for fertilizer are accounted for in the Agriculture chapter.

32 Urea is used as a nitrogenous fertilizer for agricultural applications and also in a variety of industrial applications.
33 The industrial applications of urea include its use in adhesives, binders, sealants, resins, fillers, analytical reagents,
34 catalysts, intermediates, solvents, dyestuffs, fragrances, deodorizers, flavoring agents, humectants and dehydrating
35 agents, formulation components, monomers, paint and coating additives, photosensitive agents, and surface
36 treatments agents. In addition, urea is used for abating nitrogen oxide (NO_x) emissions from coal-fired power plants
37 and diesel transportation motors.

38 Emissions of CO₂ from urea consumed for non-agricultural purposes in 2015 were estimated to be 1.1 MMT CO₂
39 Eq. (1,128 kt), and are summarized in Table 4-22 and Table 4-23. 2015 data on urea production data, urea exports

¹⁸ See <<https://www.epa.gov/ghgreporting/historical-rulemakings>>.

¹⁹ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

and imports are not yet published. 2014 data has been used as proxy for 2015. Net CO₂ emissions from urea consumption for non-agricultural purposes in 2015 have decreased by approximately 71 percent from 1990.

Table 4-22: CO₂ Emissions from Urea Consumption for Non-Agricultural Purposes (MMT CO₂ Eq.)

Source	1990	2005	2011	2012	2013	2014	2015
Urea Consumption	3.8	3.7	4.0	4.4	4.0	1.4	1.1
Total	3.8	3.7	4.0	4.4	4.0	1.4	1.1

Table 4-23: CO₂ Emissions from Urea Consumption for Non-Agricultural Purposes (kt)

Source	1990	2005	2011	2012	2013	2014	2015
Urea Consumption	3,784	3,653	4,030	4,407	4,014	1,380	1,128
Total	3,784	3,653	4,030	4,407	4,014	1,380	1,128

Methodology

Emissions of CO₂ resulting from urea consumption for non-agricultural purposes are estimated by multiplying the amount of urea consumed in the United States for non-agricultural purposes by a factor representing the amount of CO₂ used as a raw material to produce the urea. This method is based on the assumption that all of the carbon in urea is released into the environment as CO₂ during use, and consistent with the 2006 IPCC Guidelines.

The amount of urea consumed for non-agricultural purposes in the United States is estimated by deducting the quantity of urea fertilizer applied to agricultural lands, which is obtained directly from the Agriculture chapter (see Table 5-24) and is reported in Table 4-24, from the total domestic supply of urea. In previous Inventory reports, the quantity of urea fertilizer applied to agricultural lands was obtained directly from the *Cropland Remaining Cropland* section of the Land Use, Land Use Change, and Forestry chapter. The domestic supply of urea is estimated based on the amount of urea produced plus the sum of net urea imports and exports. A factor of 0.733 tons of CO₂ per ton of urea consumed is then applied to the resulting supply of urea for non-agricultural purposes to estimate CO₂ emissions from the amount of urea consumed for non-agricultural purposes. The 0.733 tons of CO₂ per ton of urea emission factor is based on the stoichiometry of producing urea from ammonia and CO₂. This corresponds to a stoichiometric CO₂/urea factor of 44/60, assuming complete conversion of NH₃ and CO₂ to urea (IPCC 2006; EFMA 2000).

Urea production data for 1990 through 2008 were obtained from the *Minerals Yearbook: Nitrogen* (USGS 1994 through 2009). Urea production data for 2009 through 2010 were obtained from the U.S. Census Bureau (2011). The U.S. Census Bureau ceased collection of urea production statistics in 2011, therefore, urea production data for 2011, 2012, 2013 and 2014 were obtained from the *Minerals Yearbook: Nitrogen* (USGS 2014 through 2016). Urea production data for 2015 are not yet publicly available and so 2014 data have been used as proxy.

Urea import data for 2015 are not yet publicly available and so 2014 data have been used as proxy. Urea import data for 2014 were obtained from the *Minerals Yearbook: Nitrogen* (USGS 2016). Urea import data for 2011 and 2012 were taken from U.S. Fertilizer Import/Exports from the United States Department of Agriculture (USDA) Economic Research Service Data Sets (U.S. Department of Agriculture 2012). Urea import data for the previous years were obtained from the U.S. Census Bureau *Current Industrial Reports Fertilizer Materials and Related Products* annual and quarterly reports for 1997 through 2010 (U.S. Census Bureau 2001 through 2011), The Fertilizer Institute (TFI 2002) for 1993 through 1996, and the United States International Trade Commission Interactive Tariff and Trade DataWeb (U.S. ITC 2002) for 1990 through 1992 (see Table 4-24). Urea export data for 2015 are not yet publicly available and so 2014 data have been used as proxy. Urea export data for 2014 were obtained from the *Minerals Yearbook: Nitrogen* (USGS 2016). Urea export data for 1990 through 2012 were taken from U.S. Fertilizer Import/Exports from USDA Economic Research Service Data Sets (U.S. Department of Agriculture 2012).

Table 4-24: Urea Production, Urea Applied as Fertilizer, Urea Imports, and Urea Exports (kt)

Year	Urea Production	Urea Applied as Fertilizer	Urea Imports	Urea Exports
1990	7,450	3,296	1,860	854
2005	5,270	4,779	5,026	536
2011	5,430	5,587	5,860	207
2012	5,220	5,819	6,944	336
2013	5,480	6,141	6,470	335
2014	5,230	6,520	3,510	339
2015	5,230	6,862	3,510	339

Uncertainty and Time-Series Consistency – TO BE UPDATED FOR FINAL INVENTORY REPORT

There is limited publicly-available data on the quantities of urea produced and consumed for non-agricultural purposes. Therefore, the amount of urea used for non-agricultural purposes is estimated based on a balance that relies on estimates of urea production, urea imports, urea exports, and the amount of urea used as fertilizer. The primary uncertainties associated with this source category are associated with the accuracy of these estimates as well as the fact that each estimate is obtained from a different data source. Because urea production estimates are no longer available from the USGS, there is additional uncertainty associated with urea produced beginning in 2011. There is also uncertainty associated with the assumption that all of the carbon in urea is released into the environment as CO₂ during use.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-25. Carbon dioxide emissions associated with urea consumption for non-agricultural purposes were estimated to be between 3.5 and 4.5 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 12 percent below and 12 percent above the emission estimate of 4.0 MMT CO₂ Eq.

Table 4-25: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Urea Consumption for Non-Agricultural Purposes (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a (MMT CO ₂ Eq.) (%)			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Urea Consumption for Non-Agricultural Purposes	CO ₂	4.0	3.5	4.5	-12%	+12%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Recalculations Discussion

Production estimates for total urea production and estimates for urea exports and imports for 2014 were updated using information obtained from the *Minerals Yearbook: Nitrogen* (USGS 2016). This update, as well as the urea consumption update included below, resulted in a significant decrease in urea imports for 2014, resulting in a decrease of the 2014 emission estimate relative to the previous report of approximately 66 percent. In addition, this update also resulted in an update to the urea export value for 2013.

The amount of urea consumed for agricultural purposes (used for calculating urea consumption for non-agricultural purposes) in the United States for the years 2011 through 2014 was revised based updated urea application estimates in a new AAPFCO report (2016) obtained from the Agriculture chapter (see Table 5-24). These updates resulted in a decrease in the emission estimate relative to the previous report of approximately 5 percent in 2013 and 66 percent in 2014, as previously described. As stated previously in the Methodology section, in previous inventory reports the quantity of urea fertilizer applied to agricultural lands was obtained directly from the *Cropland Remaining Cropland* section of the Land Use, Land Use Change, and Forestry chapter, and has been moved to the Agriculture chapter for this report.

4.7 Nitric Acid Production (IPCC Source Category 2B2)

Nitrous oxide (N₂O) is emitted during the production of nitric acid (HNO₃), an inorganic compound used primarily to make synthetic commercial fertilizers. It is also a major component in the production of adipic acid—a feedstock for nylon—and explosives. Virtually all of the nitric acid produced in the United States is manufactured by the high-temperature catalytic oxidation of ammonia (EPA 1998). There are two different nitric acid production methods: weak nitric acid and high-strength nitric acid. The first method utilizes oxidation, condensation, and absorption to produce nitric acid at concentrations between 30 and 70 percent nitric acid. High-strength acid (90 percent or greater nitric acid) can be produced from dehydrating, bleaching, condensing, and absorption of the weak nitric acid. The basic process technology for producing nitric acid has not changed significantly over time. Most U.S. plants were built between 1960 and 2000. As of 2015, there were 34 active weak nitric acid production plants, including one high-strength nitric acid production plant in the United States (EPA 2010; EPA 2016).

During this reaction, N₂O is formed as a byproduct and is released from reactor vents into the atmosphere. Emissions from fuels consumed for energy purposes during the production of nitric acid are accounted for in the Energy chapter.

Nitric acid is made from the reaction of ammonia (NH₃) with oxygen (O₂) in two stages. The overall reaction is:

Currently, the nitric acid industry controls emissions of NO and NO₂ (i.e., NO_x). As such, the industry in the United States uses a combination of non-selective catalytic reduction (NSCR) and selective catalytic reduction (SCR) technologies. In the process of destroying NO_x, NSCR systems are also very effective at destroying N₂O. However, NSCR units are generally not preferred in modern plants because of high energy costs and associated high gas temperatures. NSCR systems were installed in nitric plants built between 1971 and 1977 with NSCRs installed at approximately one-third of the weak acid production plants. U.S. facilities are using both tertiary (i.e., NSCR) and secondary controls (i.e., alternate catalysts).

Nitrous oxide emissions from this source were estimated to be 11.6 MMT CO₂ Eq. (39 kt of N₂O) in 2015 (see Table 4-26). Emissions from nitric acid production have decreased by 5 percent since 1990, with the trend in the time series closely tracking the changes in production. Emissions have decreased by 19 percent since 1997, the highest year of production in the time series.

Table 4-26: N₂O Emissions from Nitric Acid Production (MMT CO₂ Eq. and kt N₂O)

Year	MMT CO ₂ Eq.	kt N ₂ O
1990	12.1	41
2005	11.3	38
2011	10.9	37

2012	10.5	35
2013	10.7	36
2014	10.9	37
2015	11.6	39

1 Methodology

2 Emissions of N₂O were calculated using the estimation methods provided by the *2006 IPCC Guidelines* and country
 3 specific methods from EPA’s GHGRP. The *2006 IPCC Guidelines* Tier 2 method was used to estimate emissions
 4 from nitric acid production for 1990 through 2009, and a country-specific approach similar to the IPCC Tier 3
 5 method was used to estimate N₂O emissions for 2010 through 2015.

6 2010 through 2015

7 Process N₂O emissions and nitric acid production data were obtained directly from EPA’s GHGRP for 2010 through
 8 2015 by aggregating reported facility-level data (EPA 2016). In the United States, all nitric acid facilities producing
 9 weak nitric acid (30 to 70 percent in strength) are required to report annual greenhouse gas emissions data to EPA as
 10 per the requirements of its GHGRP. As of 2015, there were 34 facilities that reported to EPA, including the known
 11 single high-strength nitric acid production facility in the United States (EPA 2016). All nitric acid (weak acid)
 12 facilities are required to calculate process emissions using a site-specific emission factor developed through annual
 13 performance testing under typical operating conditions or by directly measuring N₂O emissions using monitoring
 14 equipment.²⁰ The high-strength nitric acid facility also reports N₂O emissions associated with weak acid production
 15 and this may capture all relevant emissions, pending additional further EPA research. More details on the
 16 calculation, monitoring and QA/QC methods applicable to Nitric Acid facilities can be found under Subpart V:
 17 Nitric Acid Production of the regulation, Part 98.²¹ EPA verifies annual facility-level GHGRP reports through a
 18 multi-step process (e.g., combination of electronic checks and manual reviews) to identify potential errors and
 19 ensure that data submitted to EPA are accurate, complete, and consistent.²²

20 To calculate emissions from 2010 through 2015, EPA’s GHGRP nitric acid production data is utilized to develop
 21 weighted country specific emission factors used to calculate emissions estimates. Based on aggregated nitric acid
 22 production data by abatement type (i.e., with, without) provided by EPA’s GHGRP, the percent of production values
 23 and associated emissions of nitric acid with and without abatement technologies are calculated. These percentages
 24 are the basis for developing the country specific weighted emission factors which vary from year to year based on
 25 the amount of nitric acid production with and without abatement technologies.

26 1990 through 2009

27 Using EPA’s GHGRP data for 2010,²³ country-specific N₂O emission factors were calculated for nitric acid
 28 production with abatement and without abatement (i.e., controlled and uncontrolled emission factors), as previous
 29 stated. The following 2010 emission factors were derived for production with abatement and without abatement: 3.3
 30 kg N₂O/metric ton HNO₃ produced at plants using abatement technologies (e.g., tertiary systems such as NSCR
 31 systems) and 5.99 kg N₂O/metric ton HNO₃ produced at plants not equipped with abatement technology. Country-
 32 specific weighted emission factors were derived by weighting these emission factors by percent production with
 33 abatement and without abatement over time periods 1990 through 2008 and 2009. These weighted emission factors
 34 were used to estimate N₂O emissions from nitric acid production for years prior to the availability of EPA’s GHGRP

²⁰ Facilities must use standard methods, either EPA Method 320 or ASTM D6348-03 and must follow associated QA/QC procedures consistent during these performance test consistent with category-specific QC of direct emission measurements.

²¹ See <http://www.ecfr.gov/cgi-bin/text-idx?tpl=/ecfrbrowse/Title40/40cfr98_main_02.tpl>.

²² See <https://www.epa.gov/sites/production/files/2015-07/documents/ghgrp_verification_factsheet.pdf>.

²³ National N₂O process emissions, national production, and national share of nitric acid production with abatement and without abatement technology was aggregated from the GHGRP facility-level data for 2010 to 2015 (i.e., percent production with and without abatement).

1 data (i.e., 1990 through 2008 and 2009). A separate weighted factor is included for 2009 due to data availability for
 2 that year. At that time, EPA had initiated compilation of a nitric acid database to improve estimation of emissions
 3 from this industry and obtained updated information on application of controls via review of permits and outreach
 4 with facilities and trade associations. The research indicated recent installation of abatement technologies at
 5 additional facilities.

6 Based on the available data, it was assumed that emission factors for 2010 would be more representative of
 7 operating conditions in 1990 through 2009 than more recent years. Initial review of historical data indicates that
 8 percent production with and without abatement can change over time and also year over year due to changes in
 9 application of facility-level abatement technologies, maintenance of abatement technologies, and also due to plant
 10 closures and start-ups (EPA 2012, 2013; Desai 2012; CAR 2013). The installation dates of N₂O abatement
 11 technologies are not known at most facilities, but it is assumed that facilities reporting abatement technology use
 12 have had this technology installed and operational for the duration of the time series considered in this report
 13 (especially NSCRs).

14 The country-specific weighted N₂O emission factors were used in conjunction with annual production to estimate
 15 N₂O emissions for 1990 through 2009, using the following equations:

$$E_i = P_i \times EF_{weighted,i}$$

$$EF_{weighted,i} = [(\%P_{c,i} \times EF_c) + (\%P_{unc,i} \times EF_{unc})]$$

18 where,

- 19 E_i = Annual N₂O Emissions for year i (kg/yr)
- 20 P_i = Annual nitric acid production for year i (metric tons HNO₃)
- 21 EF_{weighted,i} = Weighted N₂O emission factor for year i (kg N₂O/metric ton HNO₃)
- 22 %P_{c,i} = Percent national production of HNO₃ with N₂O abatement technology (%)
- 23 EF_c = N₂O emission factor, with abatement technology (kg N₂O/metric ton HNO₃)
- 24 %P_{unc,i} = Percent national production of HNO₃ without N₂O abatement technology (%)
- 25 EF_{unc} = N₂O emission factor, without abatement technology (kg N₂O/metric ton HNO₃)
- 26 i = year from 1990 through 2009

- 27 • For 2009: Weighted N₂O emission factor – 5.46 kg N₂O/metric ton HNO₃.
- 28 • For 1990 through 2008: Weighted N₂O emission factor – 5.66 kg N₂O/metric ton HNO₃.

29 Nitric acid production data for the United States for 1990 through 2009 were obtained from the U.S. Census Bureau
 30 (U.S. Census Bureau 2008, 2009, 2010a, 2010b) (see Table 4-27). Publicly-available information on plant-level
 31 abatement technologies was used to estimate the shares of nitric acid production with and without abatement for
 32 2008 and 2009 (EPA 2012, 2013; Desai 2012; CAR 2013). EPA has previously conducted a review of operating
 33 permits to obtain more current information due to the lack of publicly-available data on use of abatement
 34 technologies for 1990 through 2007, as stated previously; therefore, the share of national production with and
 35 without abatement for 2008 was assumed to be constant for 1990 through 2007.

36 **Table 4-27: Nitric Acid Production (kt)**

Year	kt
1990	7,200
2005	6,710

2014	7,660
2015	7,210

Uncertainty and Time-Series Consistency – TO BE UPDATED FOR FINAL INVENTORY REPORT

Uncertainty associated with the parameters used to estimate N₂O emissions includes the share of U.S. nitric acid production attributable to each emission abatement technology over the time series (especially prior to 2010), and the associated emission factors applied to each abatement technology type. While some information has been obtained through outreach with industry associations, limited information is available over the time series (especially prior to 2010) for a variety of facility level variables, including plant specific production levels, plant production technology (e.g., low, high pressure, etc.), and abatement technology type, installation date of abatement technology, and accurate destruction and removal efficiency rates. Production data prior to 2010 were obtained from National Census Bureau, which does not provide uncertainty estimates with their data. Facilities reporting to GHGRP must measure production using equipment and practices used for accounting purposes. At this time EPA does not estimate uncertainty of the aggregated facility-level information.

To maintain consistency across the time-series and with the rounding approaches taken by other data sets, a new rounding approach was performed for the GHGRP Subpart V: Nitric Acid data. This resulted in production data changes across the time-series of 2010 to 2015, in which GHGRP data has been utilized. The results of this update have had an insignificant impact on the emissions estimates across the 2010 to 2015 time-series.

The results of this Approach 2 quantitative uncertainty analysis are summarized in Table 4-28. Nitrous oxide emissions from nitric acid production were estimated to be between 10.4 and 11.5 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 5 percent below to 5 percent above the 2015 emissions estimate of 11.6 MMT CO₂ Eq.

Table 4-28: Approach 2 Quantitative Uncertainty Estimates for N₂O Emissions from Nitric Acid Production (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Nitric Acid Production	N ₂ O	11.6	10.4	11.5	-5%	+5%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Planned Improvements

Pending resources, EPA is considering both near-term and long-term improvement to estimates and associated characterization of uncertainty. In the short-term, with 6 years of EPA's GHGRP data EPA hopes to complete updates of category-specific QC procedures to potentially also improve both qualitative and quantitative uncertainty estimates. Longer term, in 2020 EPA anticipates having information from GHGRP facilities on the installation date of any N₂O abatement equipment, per recent revisions finalized in December 2016 to EPA's GHGRP. This information will enable more accurate estimation of N₂O emissions from nitric-acid production over the time-series.

4.8 Adipic Acid Production (IPCC Source Category 2B3)

Adipic acid is produced through a two-stage process during which nitrous oxide (N₂O) is generated in the second stage. Emissions from fuels consumed for energy purposes during the production of adipic acid are accounted for in the Energy chapter. The first stage of manufacturing usually involves the oxidation of cyclohexane to form a cyclohexanone/ cyclohexanol mixture. The second stage involves oxidizing this mixture with nitric acid to produce adipic acid. Nitrous oxide is generated as a byproduct of the nitric acid oxidation stage and is emitted in the waste gas stream (Thiemens and Trogler 1991). The second stage is represented by the following chemical reaction:

Process emissions from the production of adipic acid vary with the types of technologies and level of emission controls employed by a facility. In 1990, two major adipic acid-producing plants had N₂O abatement technologies in place and, as of 1998, three major adipic acid production facilities had control systems in place (Reimer et al. 1999). One small plant, which last operated in April 2006 and represented approximately two percent of production, did not control for N₂O (VA DEQ 2009; ICIS 2007; VA DEQ 2006). In 2014, catalytic reduction, non-selective catalytic reduction (NSCR) and thermal reduction abatement technologies were applied as N₂O abatement measures at adipic acid facilities (EPA 2016).

Worldwide, only a few adipic acid plants exist. The United States, Europe, and China are the major producers. In 2015, the United States had two companies with a total of three adipic acid production facilities (two in Texas and one in Florida), all of which were operational (EPA 2016). The United States accounts for the largest share of global adipic acid production capacity (30 percent), followed by the European Union (29 percent) and China (22 percent) (SEI 2010). Adipic acid is a white crystalline solid used in the manufacture of synthetic fibers, plastics, coatings, urethane foams, elastomers, and synthetic lubricants. Commercially, it is the most important of the aliphatic dicarboxylic acids, which are used to manufacture polyesters. Eighty-four percent of all adipic acid produced in the United States is used in the production of nylon 6,6; 9 percent is used in the production of polyester polyols; 4 percent is used in the production of plasticizers; and the remaining 4 percent is accounted for by other uses, including unsaturated polyester resins and food applications (ICIS 2007). Food grade adipic acid is used to provide some foods with a “tangy” flavor (Thiemens and Trogler 1991).

Nitrous oxide emissions from adipic acid production were estimated to be 4.3 MMT CO₂ Eq. (14 kt N₂O) in 2015 (see Table 4-29). National adipic acid production has increased by approximately 40 percent over the period of 1990 through 2015, to approximately 1,055,000 metric tons (ACC 2016). Over the period 1990 through 2015, emissions have been reduced by 72 percent due to both the widespread installation of pollution control measures in the late 1990s and plant idling in the late 2000s. In April 2006, the smallest of the four facilities ceased production of adipic acid (VA DEQ 2009); furthermore, one of the major adipic acid production facilities was not operational in 2009 or 2010 (Desai 2010). All three remaining facilities were in operation in 2015. Very little information on annual trends in the activity data exist for adipic acid.

Table 4-29: N₂O Emissions from Adipic Acid Production (MMT CO₂ Eq. and kt N₂O)

Year	MMT CO ₂ Eq.	kt N ₂ O
1990	15.2	51
2005	7.1	24
2011	10.2	34
2012	5.5	19
2013	3.9	13
2014	5.4	18

1 Methodology

2 Emissions are estimated using both Tier 2 and Tier 3 methods consistent with the *2006 IPCC Guidelines*. Due to
 3 confidential business information, plant names are not provided in this section. Therefore, the four adipic acid-
 4 producing facilities will be referred to as Plants 1 through 4. Plant 4 was closed in April 2006. Overall, as noted
 5 above, the three plants that are currently operating facilities use abatement equipment. Plants 1 and 2 employ
 6 catalytic destruction and Plant 3 employs thermal destruction.

7 2010 through 2015

8 All emission estimates for 2010 through 2015 were obtained through analysis of EPA’s GHGRP data (EPA 2014
 9 through 2016), which is consistent with the *2006 IPCC Guidelines* Tier 3 method. Facility-level greenhouse gas
 10 emissions data were obtained from the GHGRP for the years 2010 through 2015 (EPA 2014 through 2016) and
 11 aggregated to national N₂O emissions. Consistent with IPCC Tier 3 methods, all adipic acid production facilities are
 12 required to calculate emissions using a facility-specific emission factor developed through annual performance
 13 testing under typical operating conditions or by directly measuring N₂O emissions using monitoring equipment.²⁴
 14 More information on the calculation, monitoring and QA/QC methods for process N₂O emissions applicable to
 15 adipic acid production facilities under Subpart E can be found in the electronic code of federal regulations.²⁵ EPA
 16 verifies annual facility-level GHGRP reports through a multi-step process (e.g. combination of electronic checks and
 17 manual reviews) to identify potential errors and ensure that data submitted to EPA are accurate, complete, and
 18 consistent.²⁶

19 1990 through 2009

20 For years prior to EPA’s GHGRP reporting, for both Plants 1 and 2, 1990 to 2009 emission estimates were obtained
 21 directly from the plant engineer and account for reductions due to control systems in place at these plants during the
 22 time series. These prior estimates are considered confidential business information and hence are not published
 23 (Desai 2010). These estimates were based on continuous process monitoring equipment installed at the two
 24 facilities. In 2009 and 2010, no adipic acid production occurred at Plant 1 per reporting to EPA’s GHGRP (EPA
 25 2012; Desai 2011b).

26 For the Plant 4, 1990 through 2009 N₂O emissions were estimated using the following Tier 2 equation from the
 27 *2006 IPCC Guidelines* until shutdown of the plant in 2006:

$$28 \quad E_{aa} = Q_{aa} \times EF_{aa} \times (1 - [DF \times UF])$$

29 where,

30	E_{aa}	=	N ₂ O emissions from adipic acid production, metric tons
31	Q_{aa}	=	Quantity of adipic acid produced, metric tons
32	EF_{aa}	=	Emission factor, metric ton N ₂ O/metric ton adipic acid produced
33	DF	=	N ₂ O destruction factor
34	UF	=	Abatement system utility factor

35 The adipic acid production is multiplied by an emission factor (i.e., N₂O emitted per unit of adipic acid produced),
 36 which has been estimated, based on experiments that the reaction stoichiometry for N₂O production in the
 37 preparation of adipic acid, to be approximately 0.3 metric tons of N₂O per metric ton of product (IPCC 2006). The
 38 “N₂O destruction factor” in the equation represents the percentage of N₂O emissions that are destroyed by the

²⁴ Facilities must use standard methods, either EPA Method 320 or ASTM D6348-03 and must follow associated QA/QC procedures consistent during these performance test consistent with category-specific QC of direct emission measurements.

²⁵ See <http://www.ecfr.gov/cgi-bin/text-idx?tpl=/ecfrbrowse/Title40/40cfr98_main_02.tpl>.

²⁶ See <https://www.epa.gov/sites/production/files/2015-07/documents/ghgrp_verification_factsheet.pdf>.

1 installed abatement technology. The “abatement system utility factor” represents the percentage of time that the
 2 abatement equipment operates during the annual production period. No abatement equipment was installed at the
 3 Inolex/Allied Signal facility, which last operated in April 2006 (VA DEQ 2009). Plant-specific production data for
 4 this facility were obtained across the time series from 1990 through 2006 from the Virginia Department of
 5 Environmental Quality (VA DEQ 2010). The plant-specific production data were then used for calculating
 6 emissions as described above.

7 For Plant 3, 2005 through 2009 emissions were obtained directly from the plant (Desai 2011a). For 1990 through
 8 2004, emissions were estimated using plant-specific production data and the IPCC factors as described above for
 9 Plant 4. Plant-level adipic acid production for 1990 through 2003 was estimated by allocating national adipic acid
 10 production data to the plant level using the ratio of known plant capacity to total national capacity for all U.S. plants
 11 (ACC 2016; CMR 2001, 1998; CW 1999; C&EN 1992 through 1995). For 2004, actual plant production data were
 12 obtained and used for emission calculations (CW 2005).

13 Plant capacities for 1990 through 1994 were obtained from *Chemical & Engineering News*, “Facts and Figures” and
 14 “Production of Top 50 Chemicals” (C&EN 1992 through 1995). Plant capacities for 1995 and 1996 were kept the
 15 same as 1994 data. The 1997 plant capacities were taken from *Chemical Market Reporter*, “Chemical Profile:
 16 Adipic Acid” (CMR 1998). The 1998 plant capacities for all four plants and 1999 plant capacities for three of the
 17 plants were obtained from *Chemical Week*, Product Focus: Adipic Acid/Adiponitrile (CW 1999). Plant capacities for
 18 2000 for three of the plants were updated using *Chemical Market Reporter*, “Chemical Profile: Adipic Acid” (CMR
 19 2001). For 2001 through 2003, the plant capacities for three plants were kept the same as the year 2000 capacities.
 20 Plant capacity for 1999 to 2003 for the one remaining plant was kept the same as 1998.

21 National adipic acid production data (see Table 4-30) from 1990 through 2015 were obtained from the American
 22 Chemistry Council (ACC 2016).

23 **Table 4-30: Adipic Acid Production (kt)**

Year	kt
1990	755
2005	865
2011	840
2012	950
2013	980
2014	1,025
2015	1,055

24 **Uncertainty and Time-Series Consistency – TO BE UPDATED**
 25 **FOR FINAL INVENTORY REPORT**

26 Uncertainty associated with N₂O emission estimates includes the methods used by companies to monitor and
 27 estimate emissions. While some information has been obtained through outreach with facilities, limited information
 28 is available over the time series on these methods, abatement technology destruction and removal efficiency rates
 29 and plant specific production levels.

30 The results of this Approach 2 quantitative uncertainty analysis are summarized in Table 4-31. Nitrous oxide
 31 emissions from adipic acid production for 2015 were estimated to be between 5.2 and 5.6 MMT CO₂ Eq. at the 95
 32 percent confidence level. These values indicate a range of approximately 4 percent below to 4 percent above the
 33 2015 emission estimate of 4.3 MMT CO₂ Eq.

Table 4-31: Approach 2 Quantitative Uncertainty Estimates for N₂O Emissions from Adipic Acid Production (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Adipic Acid Production	N ₂ O	4.3	5.2	5.6	-4%	+4%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

4.9 Silicon Carbide Production and Consumption (IPCC Source Category 2B5)

Carbon dioxide (CO₂) and methane (CH₄) are emitted from the production of silicon carbide (SiC), a material used as an industrial abrasive. Silicon carbide is produced for abrasive, metallurgical, and other non-abrasive applications in the United States. Production for metallurgical and other non-abrasive applications is not available and therefore both CO₂ and CH₄ estimates are based solely upon production estimates of silicon carbide for abrasive applications. Emissions from fuels consumed for energy purposes during the production of silicon carbide are accounted for in the Energy chapter.

To produce SiC, silica sand or quartz (SiO₂) is reacted with carbon in the form of petroleum coke. A portion (about 35 percent) of the carbon contained in the petroleum coke is retained in the SiC. The remaining carbon is emitted as CO₂, CH₄, or carbon monoxide (CO). The overall reaction is shown below (but in practice it does not proceed according to stoichiometry):

Carbon dioxide is also emitted from the consumption of SiC for metallurgical and other non-abrasive applications.

Markets for manufactured abrasives, including SiC, are heavily influenced by activity in the U.S. manufacturing sector, especially in the aerospace, automotive, furniture, housing, and steel manufacturing sectors. The U.S. Geological Survey (USGS) reports that a portion (approximately 50 percent) of SiC is used in metallurgical and other non-abrasive applications, primarily in iron and steel production (USGS 2006a). As a result of the economic downturn in 2008 and 2009, demand for SiC decreased in those years. Low cost imports, particularly from China, combined with high relative operating costs for domestic producers, continue to put downward pressure on the production of SiC in the United States. However, demand for SiC consumption in the United States has recovered somewhat from its low in 2009 (USGS 2012a). Abrasive-grade silicon carbide was manufactured at a two facilities in 2015 (USGS 2016).

Carbon dioxide emissions from SiC production and consumption in 2015 were 0.2 MMT CO₂ Eq. (180 kt CO₂) (see Table 4-32 and Table 4-33). Approximately 51 percent of these emissions resulted from SiC production while the remainder resulted from SiC consumption. Methane emissions from SiC production in 2015 were 0.01 MMT CO₂ Eq. (0.4 kt CH₄) (see Table 4-32 and Table 4-33). Emissions have fluctuated in recent years, but 2015 emissions are about 52 percent lower than emissions in 1990.

1 **Table 4-32: CO₂ and CH₄ Emissions from Silicon Carbide Production and Consumption (MMT**
 2 **CO₂ Eq.)**

Year	1990	2005	2011	2012	2013	2014	2015
CO ₂	0.4	0.2	0.2	0.2	0.2	0.2	0.2
CH ₄	+	+	+	+	+	+	+
Total	0.4	0.2	0.2	0.2	0.2	0.2	0.2

+ Does not exceed 0.05 MMT CO₂ Eq.

3 **Table 4-33: CO₂ and CH₄ Emissions from Silicon Carbide Production and Consumption (kt)**

Year	1990	2005	2011	2012	2013	2014	2015
CO ₂	375	219	170	158	169	173	180
CH ₄	1	+	+	+	+	+	+

+ Does not exceed 0.5 kt.

4 Methodology

5 Emissions of CO₂ and CH₄ from the production of SiC were calculated²⁷ using the Tier 1 method provided by the
 6 *2006 IPCC Guidelines*. Annual estimates of SiC production were multiplied by the appropriate emission factor, as
 7 shown below:

$$E_{sc,CO_2} = EF_{sc,CO_2} \times Q_{sc}$$

$$E_{sc,CH_4} = EF_{sc,CH_4} \times Q_{sc} \times \left(\frac{1 \text{ metric ton}}{1000 \text{ kg}} \right)$$

10 where,

11	E_{sc,CO_2}	=	CO ₂ emissions from production of SiC, metric tons
12	EF_{sc,CO_2}	=	Emission factor for production of SiC, metric ton CO ₂ /metric ton SiC
13	Q_{sc}	=	Quantity of SiC produced, metric tons
14	E_{sc,CH_4}	=	CH ₄ emissions from production of SiC, metric tons
15	EF_{sc,CH_4}	=	Emission factor for production of SiC, kilogram CH ₄ /metric ton SiC

16

17 Emission factors were taken from the *2006 IPCC Guidelines*:

- 18 • 2.62 metric tons CO₂/metric ton SiC
- 19 • 11.6 kg CH₄/metric ton SiC

20 Emissions of CO₂ from silicon carbide consumption for metallurgical uses were calculated by multiplying the
 21 annual utilization of SiC for metallurgical uses (reported annually in the USGS *Minerals Yearbook: Silicon*) by the
 22 carbon content of SiC (31.5 percent), which was determined according to the molecular weight ratio of SiC.

23 Emissions of CO₂ from silicon carbide consumption for other non-abrasive uses were calculated by multiplying the
 24 annual SiC consumption for non-abrasive uses by the carbon content of SiC (31.5 percent). The annual SiC
 25 consumption for non-abrasive uses was calculated by multiplying the annual SiC consumption (production plus net
 26 imports) by the percent used in metallurgical and other non-abrasive uses (50 percent) (USGS 2006a) and then
 27 subtracting the SiC consumption for metallurgical use.

²⁷ EPA has not integrated aggregated facility-level GHGRP information to inform these estimates. The aggregated information (e.g., activity data and emissions) associated with silicon carbide did not meet criteria to shield underlying confidential business information (CBI) from public disclosure.

1 Production data for 1990 through 2013 were obtained from the *Minerals Yearbook: Manufactured Abrasives* (USGS
 2 1991a through 2015). Production data for 2014 and 2015 were obtained from the *Minerals Industry Surveys:
 3 Abrasives (Manufactured)* (USGS 2016). Silicon carbide consumption by major end use for 1990 through 2012 were
 4 obtained from the *Minerals Yearbook: Silicon* (USGS 1991b through 2013) (see Table 4-34). In the previous report,
 5 silicon carbide consumption data for 2013 and 2014 were not yet publicly available so 2012 data were used as
 6 proxy. In this year's report, 2013 and 2014 data are available and were recalculated to remove proxy data. 2015
 7 silicon carbide consumption data is not yet published by the USGS, resulting in the use of 2014 data as a proxy. Net
 8 imports and exports for the entire time series were obtained from the U.S. Census Bureau (2005 through 2016).

9 **Table 4-34: Production and Consumption of Silicon Carbide (Metric Tons)**

Year	Production	Consumption
1990	105,000	172,465
2005	35,000	220,149
2011	35,000	136,222
2012	35,000	114,265
2013	35,000	134,055
2014	35,000	140,733
2015	35,000	153,475

10 Uncertainty and Time-Series Consistency – TO BE UPDATED 11 FOR FINAL INVENTORY REPORT

12 There is uncertainty associated with the emission factors used because they are based on stoichiometry as opposed to
 13 monitoring of actual SiC production plants. An alternative would be to calculate emissions based on the quantity of
 14 petroleum coke used during the production process rather than on the amount of silicon carbide produced. However,
 15 these data were not available. For CH₄, there is also uncertainty associated with the hydrogen-containing volatile
 16 compounds in the petroleum coke (IPCC 2006). There is also uncertainty associated with the use or destruction of
 17 methane generated from the process in addition to uncertainty associated with levels of production, net imports,
 18 consumption levels, and the percent of total consumption that is attributed to metallurgical and other non-abrasive
 19 uses.

20 The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-35. Silicon carbide
 21 production and consumption CO₂ emissions from 2015 were estimated to be between 9 percent below and 9 percent
 22 above the emission estimate of 0.17 MMT CO₂ Eq. at the 95 percent confidence level. Silicon carbide production
 23 CH₄ emissions were estimated to be between 9 percent below and 10 percent above the emission estimate of 0.01
 24 MMT CO₂ Eq. at the 95 percent confidence level.

25 **Table 4-35: Approach 2 Quantitative Uncertainty Estimates for CH₄ and CO₂ Emissions from
 26 Silicon Carbide Production and Consumption (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Silicon Carbide Production and Consumption	CO ₂	0.17	0.16	0.19	-9%	+9%
Silicon Carbide Production	CH ₄	+	+	+	-9%	+10%

+ Does not exceed 0.05 MMT CO₂ Eq.

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

4.10 Titanium Dioxide Production (IPCC Source Category 2B6)

Titanium dioxide (TiO₂) is manufactured using one of two processes: the chloride process and the sulfate process. The chloride process uses petroleum coke and chlorine as raw materials and emits process-related carbon dioxide (CO₂). Emissions from fuels consumed for energy purposes during the production of titanium dioxide are accounted for in the Energy chapter. The chloride process is based on the following chemical reactions:

The sulfate process does not use petroleum coke or other forms of carbon as a raw material and does not emit CO₂.

The C in the first chemical reaction is provided by petroleum coke, which is oxidized in the presence of the chlorine and FeTiO₃ (rutile ore) to form CO₂. Since 2004, all TiO₂ produced in the United States has been produced using the chloride process, and a special grade of “calcined” petroleum coke is manufactured specifically for this purpose.

The principal use of TiO₂ is as a pigment in white paint, lacquers, and varnishes; it is also used as a pigment in the manufacture of plastics, paper, and other products. In 2015, U.S. TiO₂ production totaled 1,160,000 metric tons (USGS 2016). There were a total six plants producing TiO₂ in the United States—two located in Mississippi, and single plants located in Delaware, Louisiana, Ohio, and Tennessee.

Emissions of CO₂ from titanium dioxide production in 2015 were estimated to be 1.6 MMT CO₂ Eq. (1,554 kt CO₂), which represents an increase of 30 percent since 1990 (see Table 4-36). Compared to 2014, emissions from titanium dioxide production decreased by 8 percent in 2015 due to an 8 percent decrease in production.

Table 4-36: CO₂ Emissions from Titanium Dioxide (MMT CO₂ Eq. and kt)

Year	MMT CO ₂ Eq.	kt
1990	1.2	1,195
2005	1.8	1,755
2011	1.7	1,729
2012	1.5	1,528
2013	1.7	1,715
2014	1.7	1,688
2015	1.6	1,554

Methodology

Emissions of CO₂ from TiO₂ production were calculated by multiplying annual national TiO₂ production by chloride process-specific emission factors using a Tier 1 approach provided in *2006 IPCC Guidelines*. The Tier 1 equation is as follows:

$$E_{td} = EF_{td} \times Q_{td}$$

where,

1 E_{td} = CO₂ emissions from TiO₂ production, metric tons
 2 EF_{td} = Emission factor (chloride process), metric ton CO₂/metric ton TiO₂
 3 Q_{td} = Quantity of TiO₂ produced

4 Data were obtained for the total amount of TiO₂ produced each year. For years prior to 2004, it was assumed that
 5 TiO₂ was produced using the chloride process and the sulfate process in the same ratio as the ratio of the total U.S.
 6 production capacity for each process. As of 2004, the last remaining sulfate process plant in the United States
 7 closed; therefore, 100 percent of post-2004 production uses the chloride process (USGS 2005b). The percentage of
 8 production from the chloride process is estimated at 100 percent since 2004. An emission factor of 1.34 metric tons
 9 CO₂/metric ton TiO₂ was applied to the estimated chloride-process production (IPCC 2006). It was assumed that all
 10 TiO₂ produced using the chloride process was produced using petroleum coke, although some TiO₂ may have been
 11 produced with graphite or other carbon inputs.

12 The emission factor for the TiO₂ chloride process was taken from the *2006 IPCC Guidelines*. Titanium dioxide
 13 production data and the percentage of total TiO₂ production capacity that is chloride process for 1990 through 2013
 14 (see Table 4-37:) were obtained through the *Minerals Yearbook: Titanium Annual Report* (USGS 1991 through
 15 2015b). Production data for 2015 was obtained from the *Minerals Commodity Summary: Titanium and Titanium*
 16 *Dioxide* (USGS 2016).²⁸ Data on the percentage of total TiO₂ production capacity that is chloride process were not
 17 available for 1990 through 1993, so data from the 1994 USGS *Minerals Yearbook* were used for these years.
 18 Because a sulfate process plant closed in September 2001, the chloride process percentage for 2001 was estimated
 19 based on a discussion with Joseph Gambogi (2002). By 2002, only one sulfate process plant remained online in the
 20 United States and this plant closed in 2004 (USGS 2005b).

21 **Table 4-37: Titanium Dioxide Production (kt)**

Year	kt
1990	979
2005	1,310
2011	1,290
2012	1,140
2013	1,280
2014	1,260
2015	1,160

22 **Uncertainty and Time-Series Consistency – TO BE UPDATED**
 23 **FOR FINAL INVENTORY REPORT**

24 Each year, the U.S. Geological Survey (USGS) collects titanium industry data for titanium mineral and pigment
 25 production operations. If TiO₂ pigment plants do not respond, production from the operations is estimated on the
 26 basis of prior year production levels and industry trends. Variability in response rates varies from 67 to 100 percent
 27 of TiO₂ pigment plants over the time series.

28 Although some TiO₂ may be produced using graphite or other carbon inputs, information and data regarding these
 29 practices were not available. Titanium dioxide produced using graphite inputs, for example, may generate differing
 30 amounts of CO₂ per unit of TiO₂ produced as compared to that generated through the use of petroleum coke in
 31 production. While the most accurate method to estimate emissions would be to base calculations on the amount of
 32 reducing agent used in each process rather than on the amount of TiO₂ produced, sufficient data were not available
 33 to do so.

²⁸ EPA has not integrated aggregated facility-level GHGRP information for Titanium Dioxide production facilities (40 CFR Part 98 Subpart EE). The relevant aggregated information (activity data, emission factor) from these facilities did not meet criteria to shield underlying CBI from public disclosure.

As of 2004, the last remaining sulfate-process plant in the United States closed. Since annual TiO₂ production was not reported by USGS by the type of production process used (chloride or sulfate) prior to 2004 and only the percentage of total production capacity by process was reported, the percent of total TiO₂ production capacity that was attributed to the chloride process was multiplied by total TiO₂ production to estimate the amount of TiO₂ produced using the chloride process. Finally, the emission factor was applied uniformly to all chloride-process production, and no data were available to account for differences in production efficiency among chloride-process plants. In calculating the amount of petroleum coke consumed in chloride-process TiO₂ production, literature data were used for petroleum coke composition. Certain grades of petroleum coke are manufactured specifically for use in the TiO₂ chloride process; however, this composition information was not available.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-38. Titanium dioxide consumption CO₂ emissions from 2015 were estimated to be between 1.5 and 2.0 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 12 percent below and 13 percent above the emission estimate of 1.8 MMT CO₂ Eq.

Table 4-38: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Titanium Dioxide Production (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Titanium Dioxide Production	CO ₂	1.8	1.5	2.0	-12%	+13%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Recalculations Discussion

Production data for 2014 was updated relative to the previous Inventory based on recently published data in the USGS *2016 Minerals Commodity Summaries: Titanium and Titanium Dioxide* (USGS 2016). This resulted in a 4 percent decrease in 2014 CO₂ emissions from TiO₂ production relative to the previous report.

Planned Improvements

Planned improvements include researching the significance of titanium-slag production in electric furnaces and synthetic-rutile production using the Becher process in the United States. Significant use of these production processes will be included in future Inventory reports. This planned improvement is still in development by the EPA and is not included in this report. Pending available resources, EPA will also evaluate use of GHGRP data to improve category-specific QC consistent with both Volume 1, Chapter 6 of *2006 IPCC Guidelines* and the latest IPCC guidance on the use of facility-level data in national inventories.²⁹

4.11 Soda Ash Production and Consumption (IPCC Source Category 2B7)

Carbon dioxide (CO₂) is generated as a byproduct of calcining trona ore to produce soda ash, and is eventually emitted into the atmosphere. In addition, CO₂ may also be released when soda ash is consumed. Emissions from fuels consumed for energy purposes during the production and consumption of soda ash are accounted for in the Energy sector.

Calcining involves placing crushed trona ore into a kiln to convert sodium bicarbonate into crude sodium carbonate that will later be filtered into pure soda ash. The emission of CO₂ during trona-based production is based on the following reaction:

Soda ash (sodium carbonate, Na₂CO₃) is a white crystalline solid that is readily soluble in water and strongly alkaline. Commercial soda ash is used as a raw material in a variety of industrial processes and in many familiar consumer products such as glass, soap and detergents, paper, textiles, and food. (Emissions from soda ash used in glass production are reported under Section 4.3, Glass Production (IPCC Source Category 2A3). Glass production is its own source category and historical soda ash consumption figures have been adjusted to reflect this change.) After glass manufacturing, soda ash is used primarily to manufacture many sodium-based inorganic chemicals, including sodium bicarbonate, sodium chromates, sodium phosphates, and sodium silicates (USGS 2015b). Internationally, two types of soda ash are produced, natural and synthetic. The United States produces only natural soda ash and is second only to China in total soda ash production. Trona is the principal ore from which natural soda ash is made.

The United States represents about one-fourth of total world soda ash output. Only two states produce natural soda ash: Wyoming and California. Of these two states, only net emissions of CO₂ from Wyoming were calculated due to specifics regarding the production processes employed in the state.³⁰ Based on preliminary 2015 reported data, the estimated distribution of soda ash by end-use in 2015 (excluding glass production) was chemical production, 58 percent; soap and detergent manufacturing, 13 percent; distributors, 11 percent; flue gas desulfurization, 9 percent; other uses, 5 percent; water treatment, 3 percent; and pulp and paper production, 2 percent (USGS 2015b).³¹

U.S. natural soda ash is competitive in world markets because the majority of the world output of soda ash is made synthetically. Although the United States continues to be a major supplier of world soda ash, China, which surpassed the United States in soda ash production in 2003, is the world's leading producer.

In 2015, CO₂ emissions from the production of soda ash from trona were approximately 1.7 MMT CO₂ Eq. (1,714 kt CO₂). Soda ash consumption in the United States generated 1.1 MMT CO₂ Eq. (1,075 kt CO₂) in 2015. Total emissions from soda ash production and consumption in 2015 were 2.8 MMT CO₂ Eq. (2,789 kt CO₂) (see Table 4-39 and Table 4-40).

Total emissions from soda ash production and consumption in 2015 decreased by approximately 1 percent from emissions in 2014, and have stayed approximately the same as 1990 levels.

Emissions have remained relatively constant over the time series with some fluctuations since 1990. In general, these fluctuations were related to the behavior of the export market and the U.S. economy. The U.S. soda ash

³⁰ In California, soda ash is manufactured using sodium carbonate-bearing brines instead of trona ore. To extract the sodium carbonate, the complex brines are first treated with CO₂ in carbonation towers to convert the sodium carbonate into sodium bicarbonate, which then precipitates from the brine solution. The precipitated sodium bicarbonate is then calcined back into sodium carbonate. Although CO₂ is generated as a byproduct, the CO₂ is recovered and recycled for use in the carbonation stage and is not emitted. A third state, Colorado, produced soda ash until the plant was idled in 2004. The lone producer of sodium bicarbonate no longer mines trona in the state. For a brief time, sodium bicarbonate was produced using soda ash feedstocks mined in Wyoming and shipped to Colorado. Prior to 2004, because the trona was mined in Wyoming, the production numbers given by the USGS included the feedstocks mined in Wyoming and shipped to Colorado. In this way, the sodium bicarbonate production that took place in Colorado was accounted for in the Wyoming numbers.

³¹ Percentages may not add up to 100 percent due to independent rounding.

1 industry continued a trend of increased production and value in 2015 since experiencing a decline in domestic and
 2 export sales caused by adverse global economic conditions in 2009. The annual average unit value of soda ash set a
 3 record high in 2012, and soda ash exports increased as well, accounting for 55 percent of total production (USGS
 4 2015b).

5 **Table 4-39: CO₂ Emissions from Soda Ash Production and Consumption Not Associated with**
 6 **Glass Manufacturing (MMT CO₂ Eq.)**

Year	Production	Consumption	Total
1990	1.4	1.4	2.8
2005	1.7	1.3	3.0
2011	1.6	1.1	2.7
2012	1.7	1.1	2.8

2013	1,694	1,109	2,804
2014	1,685	1,143	2,827
2015	1,714	1,075	2,789

Note: Totals may not sum due to independent rounding.

9 Methodology

10 During the production process, trona ore is calcined in a rotary kiln and chemically transformed into a crude soda
 11 ash that requires further processing. Carbon dioxide and water are generated as byproducts of the calcination
 12 process. Carbon dioxide emissions from the calcination of trona can be estimated based on the chemical reaction
 13 shown above. Based on this formula, which is consistent with an IPCC Tier 1 approach, approximately 10.27 metric
 14 tons of trona are required to generate one metric ton of CO₂, or an emission factor of 0.0974 metric tons CO₂ per
 15 metric ton trona (IPCC 2006). Thus, the 17.6 million metric tons of trona mined in 2015 for soda ash production
 16 (USGS 2015b) resulted in CO₂ emissions of approximately 1.7 MMT CO₂ Eq. (1,714 kt).

17 Once produced, most soda ash is consumed in chemical and soap production, with minor amounts in pulp and paper,
 18 flue gas desulfurization, and water treatment (excluding soda ash consumption for glass manufacturing). As soda ash
 19 is consumed for these purposes, additional CO₂ is usually emitted. In these applications, it is assumed that one mole
 20 of carbon is released for every mole of soda ash used. Thus, approximately 0.113 metric tons of carbon (or 0.415
 21 metric tons of CO₂) are released for every metric ton of soda ash consumed. In future Inventories, consistent with
 22 the *2006 IPCC Guidelines for National Greenhouse Gas Inventories*, emissions from soda ash consumption in
 23 chemical production processes will be reported under Section 4.4 Other Process Uses of Carbonates (IPCC Category
 24 2A4).

1 The activity data for trona production and soda ash consumption (see Table 4-41) for 1990 to 2015 were obtained
 2 from the U.S. Geological Survey (USGS) *Minerals Yearbook for Soda Ash* (1994 through 2015b) and USGS
 3 *Mineral Industry Surveys for Soda Ash* (USGS 2016). Soda ash production and consumption data³² were collected
 4 by the USGS from voluntary surveys of the U.S. soda ash industry. The U.S. Environmental Protection Agency
 5 (EPA) will continue to analyze and assess opportunities to use facility-level data from EPA’s Greenhouse Gas
 6 Reporting Program (GHGRP) to improve the emission estimates for Soda Ash Production source category
 7 consistent with IPCC³³ and UNFCCC guidelines.

8 **Table 4-41: Soda Ash Production and Consumption Not Associated with Glass Manufacturing**
 9 **(kt)**

Year	Production ^a	Consumption ^b
1990	14,700	3,351
2005	17,000	3,144
2011	16,500	2,663
2012	17,100	2,645
2013	17,400	2,674
2014	17,300	2,754
2015	17,600	2,591

^a Soda ash produced from trona ore only.

^b Soda ash consumption is sales reported by producers which exclude imports. Historically, imported soda ash is less than 1 percent of the total U.S. consumption (Kostick 2012).

10 **Uncertainty and Time-Series Consistency – TO BE UPDATED** 11 **FOR FINAL INVENTORY REPORT**

12 Emission estimates from soda ash production have relatively low associated uncertainty levels in that reliable and
 13 accurate data sources are available for the emission factor and activity data for trona-based soda ash production.
 14 EPA plans to work with other entities to reassess the uncertainty of these emission factors and activity data based on
 15 the most recent information and data. Through EPA’s GHGRP, EPA is aware of one facility producing soda ash
 16 from a liquid alkaline feedstock process. Soda ash production data was collected by the USGS from voluntary
 17 surveys. A survey request was sent to each of the five soda ash producers, all of which responded, representing 100
 18 percent of the total production data (USGS 2016). One source of uncertainty is the purity of the trona ore used for
 19 manufacturing soda ash. The emission factor used for this estimate assumes the ore is 100 percent pure, and likely
 20 overestimates the emissions from soda ash manufacture. The average water-soluble sodium carbonate-bicarbonate
 21 content for ore mined in Wyoming ranges from 85.5 to 93.8 percent (USGS 1995). For emissions from soda ash
 22 consumption, the primary source of uncertainty, however, results from the fact that these emissions are dependent
 23 upon the type of processing employed by each end-use. Specific emission factors for each end-use are not available,
 24 so a Tier 1 default emission factor is used for all end uses. Therefore, there is uncertainty surrounding the emission
 25 factors from the consumption of soda ash. Additional uncertainty comes from the reported consumption and
 26 allocation of consumption within sectors that is collected on a quarterly basis by the USGS. Efforts have been made
 27 to categorize company sales within the correct end-use sector.

³² EPA has assessed feasibility of using emissions information (including activity data) from EPA’s GHGRP program; however at this time, the aggregated information associated with production of soda ash did not meet criteria to shield underlying confidential business information (CBI) from public disclosure.

³³ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-42. Soda Ash Production and Consumption CO₂ emissions for 2015 were estimated to be between 2.5 and 2.9 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 7 percent below and 6 percent above the emission estimate of 2.8 MMT CO₂ Eq.

Table 4-42: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Soda Ash Production and Consumption (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Soda Ash Production and Consumption	CO ₂	2.8	2.5	2.9	-7%	+6%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Planned Improvements

Time and resources permitting, soda ash consumed for other chemical uses will be extracted from the current soda ash consumption emission estimates and included under those sources or Other Process Uses of Carbonates (IPCC Category 2A4) for the final report of the current Inventory cycle (i.e., 1990 through 2015). In addition, EPA plans to incorporate the use of EPA’s GHGRP data for conducting category-specific QC of emission estimates consistent with both Volume 1, Chapter 6 of 2006 IPCC Guidelines and the latest IPCC guidance on the use of facility-level data in national inventories.³⁴

4.12 Petrochemical Production (IPCC Source Category 2B8)

The production of some petrochemicals results in the release of small amounts of carbon dioxide (CO₂) and methane (CH₄) emissions. Petrochemicals are chemicals isolated or derived from petroleum or natural gas. Carbon dioxide emissions from the production of acrylonitrile, carbon black, ethylene, ethylene dichloride, ethylene oxide, and methanol, and CH₄ emissions from the production of methanol and acrylonitrile are presented here and reported under IPCC Source Category 2B8. The petrochemical industry uses primary fossil fuels (i.e., natural gas, coal, petroleum, etc.) for non-fuel purposes in the production of carbon black and other petrochemicals. Emissions from fuels and feedstocks transferred out of the system for use in energy purposes (e.g., indirect or direct process heat or steam production) are currently accounted for in the Energy sector.

Worldwide more than 90 percent of acrylonitrile (vinyl cyanide, C₃H₃N) is made by way of direct ammoxidation of propylene with ammonia (NH₃) and oxygen over a catalyst. This process is referred to as the SOHIO process after the Standard Oil Company of Ohio (SOHIO) (IPCC 2006). The primary use of acrylonitrile is as the raw material for the manufacture of acrylic and modacrylic fibers. Other major uses include the production of plastics (acrylonitrile-butadiene-styrene [ABS] and styrene-acrylonitrile [SAN]), nitrile rubbers, nitrile barrier resins, adiponitrile, and acrylamide. All U.S. acrylonitrile facilities use the SOHIO process (AN 2014). The SOHIO process involves a fluidized bed reaction of chemical-grade propylene, ammonia, and oxygen over a catalyst. The process produces acrylonitrile as its primary product and the process yield depends on the type of catalyst used and the

³⁴ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

1 process configuration. The ammoxidation process also produces byproduct CO₂, carbon monoxide (CO), and water
2 from the direct oxidation of the propylene feedstock, and produces other hydrocarbons from side reactions in the
3 ammoxidation process.

4 Carbon black is a black powder generated by the incomplete combustion of an aromatic petroleum- or coal-based
5 feedstock at a high temperature. Most carbon black produced in the United States is added to rubber to impart
6 strength and abrasion resistance, and the tire industry is by far the largest consumer. The other major use of carbon
7 black is as a pigment. The predominant process used in the United States is the furnace black (or oil furnace)
8 process. In the furnace black process, carbon black oil (a heavy aromatic liquid) is continuously injected into the
9 combustion zone of a natural gas-fired furnace. Furnace heat is provided by the natural gas and a portion of the
10 carbon black feedstock; the remaining portion of the carbon black feedstock is pyrolyzed to carbon black. The
11 resultant CO₂ and uncombusted CH₄ emissions are released from thermal incinerators used as control devices,
12 process dryers, and equipment leaks. Carbon black is also produced in the United States by the thermal cracking of
13 acetylene-containing feedstocks (i.e., acetylene black process), by the thermal cracking of other hydrocarbons (i.e.,
14 thermal black process), and by the open burning of carbon black feedstock (i.e., lamp black process); each of these
15 process are used at only one U.S. plant each (EPA 2000).

16 Ethylene (C₂H₄) is consumed in the production processes of the plastics industry including polymers such as high,
17 low, and linear low density polyethylene (HDPE, LDPE, LLDPE); polyvinyl chloride (PVC); ethylene dichloride;
18 ethylene oxide; and ethylbenzene. Virtually all ethylene is produced from steam cracking of ethane, propane, butane,
19 naphtha, gas oil, and other feedstocks. The representative chemical equation for steam cracking of ethane to ethylene
20 is shown below:

21
22 Small amounts of CH₄ are also generated from the steam cracking process. In addition, CO₂ and CH₄ emissions are
23 also generated from combustion units.

24 Ethylene dichloride (C₂H₄Cl₂) is used to produce vinyl chloride monomer, which is the precursor to polyvinyl
25 chloride (PVC). Ethylene dichloride was used as a fuel additive until 1996 when leaded gasoline was phased out.
26 Ethylene dichloride is produced from ethylene by either direct chlorination, oxychlorination, or a combination of the
27 two processes (i.e., the “balanced process”); most U.S. facilities use the balanced process. The direct chlorination
28 and oxychlorination reactions are shown below:

31
32 In addition to the byproduct CO₂ produced from the direct oxidation of the ethylene feedstock, CO₂ and CH₄
33 emissions are also generated from combustion units.

34 Ethylene oxide (C₂H₄O) is used in the manufacture of glycols, glycol ethers, alcohols, and amines. Approximately
35 70 percent of ethylene oxide produced worldwide is used in the manufacture of glycols, including monoethylene
36 glycol. Ethylene oxide is produced by reacting ethylene with oxygen over a catalyst. The oxygen may be supplied to
37 the process through either an air (air process) or a pure oxygen stream (oxygen process). The byproduct CO₂ from
38 the direct oxidation of the ethylene feedstock is removed from the process vent stream using a recycled carbonate
39 solution, and the recovered CO₂ may be vented to the atmosphere or recovered for further utilization in other
40 sectors, such as food production (IPCC 2006). The combined ethylene oxide reaction and byproduct CO₂ reaction is
41 exothermic and generates heat, which is recovered to produce steam for the process. The ethylene oxide process also
42 produces other liquid and off-gas byproducts (e.g., ethane, etc.) that may be burned for energy recovery within the
43 process. Almost all facilities, except one in Texas, use the oxygen process to manufacture ethylene oxide (EPA
44 2008).

45 Methanol (CH₃OH) is a chemical feedstock most often converted into formaldehyde, acetic acid and olefins. It is
46 also an alternative transportation fuel, as well as an additive used by municipal wastewater treatment facilities in the
47 denitrification of wastewater. Methanol is most commonly synthesized from a synthesis gas (i.e., “syngas” – a
48 mixture containing H₂, CO, and CO₂) using a heterogeneous catalyst. There are a number of process techniques that
49 can be used to produce syngas. Worldwide, steam reforming of natural gas is the most common method; however, in

1 the United States only two facilities use steam reforming of natural gas. Other syngas production processes in the
 2 United States include partial oxidation of natural gas and coal gasification.

3 Emissions of CO₂ and CH₄ from petrochemical production in 2015 were 28.1 MMT CO₂ Eq. (28,062 kt CO₂) and
 4 0.2 MMT CO₂ Eq. (7 kt CH₄), respectively (see Table 4-43 and Table 4-44). Since 1990, total CO₂ emissions from
 5 petrochemical production increased by 32 percent. Methane emissions from petrochemical (methanol and
 6 acrylonitrile) production have decreased by approximately 18 percent since 1990, given declining production.

7 **Table 4-43: CO₂ and CH₄ Emissions from Petrochemical Production (MMT CO₂ Eq.)**

Year	1990	2005	2011	2012	2013	2014	2015
CO ₂	21.3	27.0	26.3	26.5	26.4	26.5	28.1
CH ₄	0.2	0.1	+	0.1	0.1	0.1	0.2
Total	21.5	27.1	26.4	26.6	26.5	26.6	28.3

+ Does not exceed 0.05 MMT CO₂ Eq.

Note: Totals may not sum due to independent rounding.

8

9 **Table 4-44: CO₂ and CH₄ Emissions from Petrochemical Production (kt)**

Year	1990	2005	2011	2012	2013	2014	2015
CO ₂	21,326	26,972	26,338	26,501	26,395	26,496	28,062
CH ₄	9	3	2	3	3	5	7

10 Methodology

11 Emissions of CO₂ and CH₄ were calculated using the estimation methods provided by the *2006 IPCC Guidelines*
 12 and country-specific methods from EPA's Greenhouse Gas Reporting Program (GHGRP). The *2006 IPCC*
 13 *Guidelines* Tier 1 method was used to estimate CO₂ and CH₄ emissions from production of acrylonitrile and
 14 methanol,³⁵ and a country-specific approach similar to the IPCC Tier 2 method was used to estimate CO₂ emissions
 15 from carbon black, ethylene, ethylene oxide, and ethylene dichloride. The Tier 2 method for petrochemicals is a total
 16 feedstock C mass balance method used to estimate total CO₂ emissions, but is not applicable for estimating CH₄
 17 emissions. As noted in the *2006 IPCC Guidelines*, the total feedstock C mass balance method (Tier 2) is based on
 18 the assumption that all of the C input to the process is converted either into primary and secondary products or into
 19 CO₂. Further, the guideline states that while the total C mass balance method estimates total C emissions from the
 20 process but does not directly provide an estimate of the amount of the total C emissions emitted as CO₂, CH₄, or
 21 non-CH₄ volatile organic compounds (NMVOCs). This method accounts for all the C as CO₂, including CH₄. Note,
 22 a subset of facilities reporting under EPA's GHGRP use alternate methods to the C balance approach (e.g.,
 23 Continuous Emission Monitoring Systems (CEMS) or other engineering approaches) to monitor CO₂ emissions and
 24 these facilities are required to also report CH₄ and N₂O emissions. Preliminary analysis of aggregated annual reports
 25 shows that these emissions are less than 500 kt/year. EPA's GHGRP is currently reviewing this data to facilitate
 26 category-specific QC and EPA plans to include in the final report (i.e., 1990 through 2015), pending completion of
 27 the analysis, time and resources.

28 Carbon Black, Ethylene, Ethylene Dichloride and Ethylene Oxide

29 2010 through 2015

30 Carbon dioxide emissions and national production were aggregated directly from EPA's GHGRP dataset for 2010
 31 through 2015 (EPA GHGRP 2016). In 2015, EPA's GHGRP data reported CO₂ emissions of 3,260,000 metric tons

³⁵ EPA has not integrated aggregated facility-level GHGRP information for acrylonitrile and methanol production. The aggregated information associated with production of these petrochemicals did not meet criteria to shield underlying CBI from public disclosure.

1 from carbon black production; 20,100,000 metric tons of CO₂ from ethylene production; 398,000 metric tons of CO₂
2 from ethylene dichloride production; and 1,200,000 metric tons of CO₂ from ethylene oxide production. These
3 emissions reflect application of a country-specific approach similar to the IPCC Tier 2 method and were used to
4 estimate CO₂ emissions from the production of carbon black, ethylene, ethylene dichloride, and ethylene oxide.
5 Since 2010, EPA's GHGRP, under Subpart X, requires all domestic producers of petrochemicals to report annual
6 emissions and supplemental emissions information (e.g., production data, etc.) to facilitate verification of reported
7 emissions. Under EPA's GHGRP, petrochemical production facilities are required to use either a mass balance
8 approach or CEMS to measure and report emissions for each petrochemical process unit to estimate facility-level
9 process CO₂ emissions. The mass balance method is used by most facilities³⁶ and assumes that all the carbon input
10 is converted into primary and secondary products, byproducts, or is emitted to the atmosphere as CO₂. To apply the
11 mass balance, facilities must measure the volume or mass of each gaseous and liquid feedstock and product, mass
12 rate of each solid feedstock and product, and carbon content of each feedstock and product for each process unit and
13 sum for their facility. More details on the greenhouse gas calculation, monitoring and QA/QC methods applicable to
14 petrochemical facilities can be found under Subpart X (Petrochemical Production) of the regulation (40 CFR Part
15 98).³⁷ EPA verifies annual facility-level GHGRP reports through a multi-step process (e.g. combination of
16 electronic checks and manual reviews) to identify potential errors and ensure that data submitted to EPA are
17 accurate, complete, and consistent.³⁸

18 1990 through 2009

19 For prior years, for these petrochemical types, an average national CO₂ emission factor was calculated based on the
20 2010 through 2013 EPA's GHGRP data and applied to production for earlier years in the time series (i.e., 1990
21 through 2009) to estimate CO₂ emissions from carbon black, ethylene, ethylene dichloride, and ethylene oxide.
22 Carbon dioxide emission factors were derived from EPA's GHGRP data by dividing annual CO₂ emissions for
23 petrochemical type "i" with annual production for petrochemical type "i" and then averaging the derived emission
24 factors obtained for each calendar year 2010 through 2015. The average emission factors for each petrochemical
25 type were applied across all prior years because petrochemical production processes in the United States have not
26 changed significantly since 1990, though some operational efficiencies have been implemented at facilities over the
27 time series.

28 The average country-specific CO₂ emission factors that were calculated from the 2010 through 2015 GHGRP data
29 are as follows:

- 30 • 2.62 metric tons CO₂/metric ton carbon black produced
 - 31 • 0.78 metric tons CO₂/metric ton ethylene produced
 - 32 • 0.040 metric tons CO₂/metric ton ethylene dichloride produced
 - 33 • 0.44 metric tons CO₂/metric ton ethylene oxide produced
- 34

35 Annual production data for carbon black for 1990 through 2009 were obtained from the International Carbon Black
36 Association (Johnson 2003 and 2005 through 2010). Annual production data for ethylene and ethylene dichloride for

³⁶ A few facilities producing ethylene dichloride used CO₂ CEMS, those CO₂ emissions have been included in the aggregated GHGRP emissions presented here. For ethylene production processes, nearly all process emissions are from the combustion of process off-gas. Under EPA's GHGRP, Subpart X, ethylene facilities can report CO₂ emissions from burning of process gases using the optional combustion methodology for ethylene production processes, which is requires estimating emissions based on fuel quantity and carbon contents of the fuel. This is consistent with the *2006 IPCC Guidelines* (p. 3.57) which recommends including combustion emissions from fuels obtained from feedstocks (e.g., off-gases) in petrochemical production under in the IPPU sector. In 2014, for example, this represented about 20 of the 80 reporting facilities. In addition to CO₂, these facilities are required to report emissions of CH₄ and N₂O from combustion of ethylene process off-gas in flares. Both facilities using CEMS (consistent with a Tier 3 approach) and those using the optional combustion methodology are also required to report emissions of CH₄ and N₂O from combustion of petrochemical process-off gases and flares, as applicable. Preliminary analysis of the aggregated reported CH₄ and N₂O emissions from facilities using CEMS and the optional combustion methodology suggests that these annual emissions are less than 500 kt/yr so not significant enough to prioritize for inclusion in the report at this time. Pending resources and significance, EPA may include these emissions in future reports to enhance completeness.

³⁷ See <http://www.ecfr.gov/cgi-bin/text-idx?tpl=/ecfrbrowse/Title40/40cfr98_main_02.tpl>.

³⁸ See <https://www.epa.gov/sites/production/files/2015-07/documents/ghgrp_verification_factsheet.pdf>.

1 1990 through 2009 were obtained from the American Chemistry Council's (ACC's) *Guide to the Business of*
 2 *Chemistry* (ACC 2002, 2003, 2005 through 2011). Annual production data for ethylene oxide were obtained from
 3 ACC's *U.S. Chemical Industry Statistical Handbook* for 2003 through 2009 (ACC 2014a) and from ACC's *Business*
 4 *of Chemistry* for 1990 through 2002 (ACC 2014b). As noted above, annual 2010 through 2015 production data for
 5 carbon black, ethylene, ethylene dichloride, and ethylene oxide, were obtained from EPA's GHGRP.

6 Acrylonitrile

7 Carbon dioxide and methane emissions from acrylonitrile production were estimated using the Tier 1 method in the
 8 *2006 IPCC Guidelines*. Annual acrylonitrile production data were used with IPCC default Tier 1 CO₂ and CH₄
 9 emission factors to estimate emissions for 1990 through 2015. Emission factors used to estimate acrylonitrile
 10 production emissions are as follows:

- 11 • 0.18 kg CH₄/metric ton acrylonitrile produced
- 12 • 1.00 metric tons CO₂/metric ton acrylonitrile produced

13
 14 Annual acrylonitrile production data for 1990 through 2015 were obtained from ACC's *Business of Chemistry* (ACC
 15 2016).

16 Methanol

17 Carbon dioxide and methane emissions from methanol production were estimated using Tier 1 method in the *2006*
 18 *IPCC Guidelines*. Annual methanol production data were used with IPCC default Tier 1 CO₂ and CH₄ emission
 19 factors to estimate emissions for 1990 through 2015. Emission factors used to estimate methanol production
 20 emissions are as follows:

- 21 • 2.3 kg CH₄/metric ton methanol produced
- 22 • 0.67 metric tons CO₂/metric ton methanol produced

23
 24 Annual methanol production data for 1990 through 2015 were obtained from the ACC's *Business of Chemistry*
 25 (ACC 2016).

26 **Table 4-45: Production of Selected Petrochemicals (kt)**

Chemical	1990	2005	2011	2012	2013	2014	2015
Carbon Black	1,307	1,651	1,340	1,280	1,230	1,210	1,220
Ethylene	16,542	23,975	25,100	24,800	25,300	25,500	26,900
Ethylene Dichloride	6,283	11,260	8,620	11,300	11,500	11,300	11,300
Ethylene Oxide	2,429	3,220	3,010	3,110	3,150	3,140	3,240
Acrylonitrile	1,214	1,325	1,055	1,220	1,075	1,095	1,050
Methanol	3,750	1,225	700	995	1,235	2,105	3,065

27 Uncertainty and Time-Series Consistency – TO BE UPDATED 28 FOR FINAL INVENTORY REPORT

29 The CH₄ and CO₂ emission factors used for acrylonitrile and methanol production are based on a limited number of
 30 studies. Using plant-specific factors instead of default or average factors could increase the accuracy of the emission
 31 estimates; however, such data were not available for the current Inventory report.

32 The results of the quantitative uncertainty analysis for the CO₂ emissions from carbon black production, ethylene,
 33 ethylene dichloride, and ethylene oxide are based on reported GHGRP data. Refer to the Methodology section for
 34 more details on how these emissions were calculated and reported to EPA's GHGRP. There is some uncertainty in
 35 the applicability of the average emission factors for each petrochemical type across all prior years. While
 36 petrochemical production processes in the United States have not changed significantly since 1990, some
 37 operational efficiencies have been implemented at facilities over the time series.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-46. Petrochemical production CO₂ emissions from 2015 were estimated to be between 25.3 and 27.8 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 5 percent below to 5 percent above the emission estimate of 26.5 MMT CO₂ Eq. Petrochemical production CH₄ emissions from 2015 were estimated to be between 0.05 and 0.15 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 55 percent below to 45 percent above the emission estimate of 0.1 MMT CO₂ Eq.

Table 4-46: Approach 2 Quantitative Uncertainty Estimates for CH₄ Emissions from Petrochemical Production and CO₂ Emissions from Carbon Black Production (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Petrochemical Production	CO ₂	26.5	25.3	27.8	-5%	+5%
Petrochemical Production	CH ₄	0.1	0.05	0.15	-55%	+45%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Recalculation Discussion

CO₂ emissions data were obtained from the EPA's GHGRP CBI aggregation analysis and updated from 2010 through 2015. In addition, this update included adjusted rounding and altering of significant figures for these years. As a result of the rounding, some reported petrochemical emissions in metric tons (MT CO₂) increased and some decreases across the 2010 to 2015 time series; however, when converted to million metric tons (MMT CO₂) this change became insignificant in its effect on total annual emissions compared to the previous Inventory report.

Planned Improvements

Improvements include completing category-specific QC of activity data and EFs, along with further assessment of CH₄ and N₂O emissions to enhance completeness in reporting of emissions from petrochemical production, pending resources, significance and time series consistency considerations.

Pending resources, a secondary potential improvement for this source category would focus on continuing to analyze the fuel and feedstock data from EPA's GHGRP to better disaggregate energy-related emissions and allocate them more accurately between the Energy and IPPU sectors of the Inventory. Some degree of double counting may occur between CO₂ estimates of non-energy use of fuels in the energy sector and CO₂ process emissions from petrochemical production in this sector. Data integration is not feasible at this time as feedstock data from the Energy Information Administration (EIA) used to estimate non-energy uses of fuels are aggregated by fuel type, rather than disaggregated by both fuel type and particular industries (e.g., petrochemical production). EPA, through its GHGRP, currently does not collect complete data on quantities of fuel consumed as feedstocks by petrochemical producers, only feedstock type. Recent revisions to reporting requirements finalized in 2014 and 2016 (79 FR 63750; 81 FR 89188)³⁹ may address this issue in future reporting years for the GHGRP data allowing for easier data integration between the non-energy uses of fuels category and the petrochemicals category presented in

³⁹ <https://www.epa.gov/ghgreporting/historical-rulemakings>

1 this chapter. EPA’s GHGRP has initiated analysis of reported petrochemical feedstocks but further QC is required.
2 This planned improvement is currently under development and has not been instituted into the current Inventory.

3 4.13 HCFC-22 Production (IPCC Source 4 Category 2B9a) – TO BE UPDATED FOR 5 FINAL INVENTORY REPORT

6 Trifluoromethane (HFC-23 or CHF₃) is generated as a byproduct during the manufacture of chlorodifluoromethane
7 (HCFC-22), which is primarily employed in refrigeration and air conditioning systems and as a chemical feedstock
8 for manufacturing synthetic polymers. Between 1990 and 2000, U.S. production of HCFC-22 increased significantly
9 as HCFC-22 replaced chlorofluorocarbons (CFCs) in many applications. Between 2000 and 2007, U.S. production
10 fluctuated but generally remained above 1990 levels. In 2008 and 2009, U.S. production declined markedly and has
11 remained near 2009 levels since. Because HCFC-22 depletes stratospheric ozone, its production for non-feedstock
12 uses is scheduled to be phased out by 2020 under the U.S. Clean Air Act.⁴⁰ Feedstock production, however, is
13 permitted to continue indefinitely.

14 HCFC-22 is produced by the reaction of chloroform (CHCl₃) and hydrogen fluoride (HF) in the presence of a
15 catalyst, SbCl₅. The reaction of the catalyst and HF produces SbCl_xF_y, (where x + y = 5), which reacts with
16 chlorinated hydrocarbons to replace chlorine atoms with fluorine. The HF and chloroform are introduced by
17 submerged piping into a continuous-flow reactor that contains the catalyst in a hydrocarbon mixture of chloroform
18 and partially fluorinated intermediates. The vapors leaving the reactor contain HCFC-21 (CHCl₂F), HCFC-22
19 (CHClF₂), HFC-23 (CHF₃), HCl, chloroform, and HF. The under-fluorinated intermediates (HCFC-21) and
20 chloroform are then condensed and returned to the reactor, along with residual catalyst, to undergo further
21 fluorination. The final vapors leaving the condenser are primarily HCFC-22, HFC-23, HCl and residual HF. The
22 HCl is recovered as a useful byproduct, and the HF is removed. Once separated from HCFC-22, the HFC-23 may be
23 released to the atmosphere, recaptured for use in a limited number of applications, or destroyed.

24 Two facilities produced HCFC-22 in the U.S. in 2014. Emissions of HFC-23 from this activity in 2014 were
25 estimated to be 5.0 MMT CO₂ Eq. (0.3 kt) (see Table 4-47). This quantity represents a 23 percent increase from
26 2013 emissions and an 89 percent decline from 1990 emissions. The increase from 2013 emissions and the decrease
27 from 1990 emissions were caused primarily by changes in the HFC-23 emission rate (kg HFC-23 emitted/kg HCFC-
28 22 produced). The long-term decrease in the emission rate is primarily attributable to six factors: (a) five plants that
29 did not capture and destroy the HFC-23 generated have ceased production of HCFC-22 since 1990; (b) one plant
30 that captures and destroys the HFC-23 generated began to produce HCFC-22; (c) one plant implemented and
31 documented a process change that reduced the amount of HFC-23 generated; (d) the same plant began recovering
32 HFC-23, primarily for destruction and secondarily for sale; (e) another plant began destroying HFC-23; and (f) the
33 same plant, whose emission factor was higher than that of the other two plants, ceased production of HCFC-22 in
34 2013.

35 **Table 4-47: HFC-23 Emissions from HCFC-22 Production (MMT CO₂ Eq. and kt HFC-23)**

Year	MMT CO ₂ Eq.	kt HFC-23
1990	46.1	3
2005	20.0	1
2010	8.0	0.5
2011	8.8	0.6
2012	5.5	0.4

⁴⁰ As construed, interpreted, and applied in the terms and conditions of the Montreal Protocol on Substances that Deplete the Ozone Layer. [42 U.S.C. §7671m(b), CAA §614]

2013	4.1	0.3
2014	5.0	0.3

Methodology

To estimate HFC-23 emissions for five of the eight HCFC-22 plants that have operated in the United States since 1990, methods comparable to the Tier 3 methods in the *2006 IPCC Guidelines* (IPCC 2006) were used. Emissions for 2010 through 2014 were obtained through reports submitted by U.S. HCFC-22 production facilities to EPA's Greenhouse Gas Reporting Program (GHGRP). EPA's GHGRP mandates that all HCFC-22 production facilities report their annual emissions of HFC-23 from HCFC-22 production processes and HFC-23 destruction processes. Previously, data were obtained by EPA through collaboration with an industry association that received voluntarily reported HCFC-22 production and HFC-23 emissions annually from all U.S. HCFC-22 producers from 1990 through 2009. These emissions were aggregated and reported to EPA on an annual basis.

For the other three plants, the last of which closed in 1993, methods comparable to the Tier 1 method in the *2006 IPCC Guidelines* were used. Emissions from these three plants have been calculated using the recommended emission factor for unoptimized plants operating before 1995 (0.04 kg HCFC-23/kg HCFC-22 produced).

The five plants that have operated since 1994 measure (or, for the plants that have since closed, measured) concentrations of HFC-23 to estimate their emissions of HFC-23. Plants using thermal oxidation to abate their HFC-23 emissions monitor the performance of their oxidizers to verify that the HFC-23 is almost completely destroyed. Plants that release (or historically have released) some of their byproduct HFC-23 periodically measure HFC-23 concentrations in the output stream using gas chromatography. This information is combined with information on quantities of products (e.g., HCFC-22) to estimate HFC-23 emissions.

To estimate 1990 through 2009 emissions, reports from an industry association were used that aggregated HCFC-22 production and HFC-23 emissions from all U.S. HCFC-22 producers and reported them to EPA (ARAP 1997, 1999, 2000, 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010). To estimate 2010 through 2014 emissions, facility-level data (including both HCFC-22 production and HFC-23 emissions) reported through the EPA's GHGRP were analyzed. In 1997 and 2008, comprehensive reviews of plant-level estimates of HFC-23 emissions and HCFC-22 production were performed (RTI 1997; RTI 2008). The 1997 and 2008 reviews enabled U.S. totals to be reviewed, updated, and where necessary, corrected, and also for plant-level uncertainty analyses (Monte-Carlo simulations) to be performed for 1990, 1995, 2000, 2005, and 2006. Estimates of annual U.S. HCFC-22 production are presented in Table 4-48.

Table 4-48: HCFC-22 Production (kt)

Year	kt
1990	139
2005	156
2010	101
2011	110
2012	96
2013	C
2014	C

Note: HCFC-22 production in 2013 and 2014 is considered Confidential Business Information (CBI) as there were only two producers of HCFC-22 in 2013 and 2014.

Uncertainty and Time-Series Consistency

The uncertainty analysis presented in this section was based on a plant-level Monte Carlo Stochastic Simulation for 2006. The Monte Carlo analysis used estimates of the uncertainties in the individual variables in each plant's estimating procedure. This analysis was based on the generation of 10,000 random samples of model inputs from the

probability density functions for each input. A normal probability density function was assumed for all measurements and biases except the equipment leak estimates for one plant; a log-normal probability density function was used for this plant’s equipment leak estimates. The simulation for 2006 yielded a 95-percent confidence interval for U.S. emissions of 6.8 percent below to 9.6 percent above the reported total.

The relative errors yielded by the Monte Carlo Stochastic Simulation for 2006 were applied to the U.S. emission estimate for 2014. The resulting estimates of absolute uncertainty are likely to be reasonably accurate because (1) the methods used by the three plants to estimate their emissions are not believed to have changed significantly since 2006, and (2) although the distribution of emissions among the plants may have changed between 2006 and 2014 (because both HCFC-22 production and the HFC-23 emission rate declined significantly), the two plants that contribute significantly to emissions were estimated to have similar relative uncertainties in their 2006 (as well as 2005) emission estimates. Thus, changes in the relative contributions of these two plants to total emissions are not likely to have a large impact on the uncertainty of the national emission estimate.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-49. HFC-23 emissions from HCFC-22 production were estimated to be between 4.7 and 5.5 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 7 percent below and 10 percent above the emission estimate of 5.0 MMT CO₂ Eq.

Table 4-49: Approach 2 Quantitative Uncertainty Estimates for HFC-23 Emissions from HCFC-22 Production (MMT CO₂ Eq. and Percent)

Source	Gas	2014 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
HCFC-22 Production	HFC-23	5.0	4.7	5.5	-7%	+10%

^a Range of emissions reflects a 95 percent confidence interval.

Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

4.14 Carbon Dioxide Consumption (IPCC Source Category 2B10)

Carbon dioxide (CO₂) is used for a variety of commercial applications, including food processing, chemical production, carbonated beverage production, and refrigeration, and is also used in petroleum production for enhanced oil recovery (EOR). Carbon dioxide used for EOR is injected underground to enable additional petroleum to be produced. For the purposes of this analysis, CO₂ used in commercial applications other than EOR is assumed to be emitted to the atmosphere. Carbon dioxide used in EOR applications is discussed in the Energy chapter under “Carbon Capture and Storage, including Enhanced Oil Recovery” and is not discussed in this section.

Carbon dioxide is produced from naturally-occurring CO₂ reservoirs, as a byproduct from the energy and industrial production processes (e.g., ammonia production, fossil fuel combustion, ethanol production), and as a byproduct from the production of crude oil and natural gas, which contain naturally occurring CO₂ as a component. Only CO₂ produced from naturally occurring CO₂ reservoirs, and as a byproduct from energy and industrial processes, and used in industrial applications other than EOR is included in this analysis. Carbon dioxide captured from biogenic sources (e.g., ethanol production plants) is not included in the Inventory. Carbon dioxide captured from crude oil and gas production is used in EOR applications and is therefore reported in the Energy chapter.

Carbon dioxide is produced as a byproduct of crude oil and natural gas production. This CO₂ is separated from the crude oil and natural gas using gas processing equipment, and may be emitted directly to the atmosphere, or captured and reinjected into underground formations, used for EOR, or sold for other commercial uses. A further

1 discussion of CO₂ used in EOR is described in the Energy chapter in Box 3-7 titled “Carbon Dioxide Transport,
2 Injection, and Geological Storage.”

3 In 2015, the amount of CO₂ produced and captured for commercial applications and subsequently emitted to the
4 atmosphere was 4.3 MMT CO₂ Eq. (4,296 kt) (see Table 4-50). This is a decrease of approximately 4 percent from
5 2014 levels and an increase of approximately 192 percent since 1990. The 2015 emissions estimate is based on a
6 linear extrapolation correlated with the trend found in the EPA’s GHGRP data, as described in the Methodology
7 section below.

8 **Table 4-50: CO₂ Emissions from CO₂ Consumption (MMT CO₂ Eq. and kt)**

Year	MMT CO ₂ Eq.	kt
1990	1.5	1,472
2005	1.4	1,375
2011	4.1	4,083
2012	4.0	4,019
2013	4.2	4,188
2014	4.5	4,471
2015	4.3	4,296

9 Methodology

10 Carbon dioxide emission estimates for 1990 through 2015 were based on the quantity of CO₂ extracted and
11 transferred for industrial applications (i.e., non-EOR end-uses). Some of the CO₂ produced by these facilities is used
12 for EOR and some is used in other commercial applications (e.g., chemical manufacturing, food production). It is
13 assumed that 100 percent of the CO₂ production used in commercial applications other than EOR is eventually
14 released into the atmosphere.

15 2010 through 2015

16 For 2010 through 2014, data from EPA’s Greenhouse Gas Reporting Program (GHGRP) (Subpart PP) were
17 aggregated from facility-level reports to develop a national-level estimate for use in the Inventory (EPA GHGRP
18 2016). Facilities report CO₂ extracted or produced from natural reservoirs and industrial sites, and CO₂ captured
19 from energy and industrial processes and transferred to various end-use applications to EPA’s GHGRP. This
20 analysis includes only reported CO₂ transferred to food and beverage end-uses. EPA is continuing to analyze and
21 assess integration of CO₂ transferred to other end-uses to enhance the completeness of estimates under this source
22 category. Other end-uses include industrial applications, such as metal fabrication. EPA is analyzing the information
23 reported to ensure that other end-use data excludes non-emissive applications and publication will not reveal
24 confidential business information (CBI). Reporters subject to EPA’s GHGRP Subpart PP are also required to report
25 the quantity of CO₂ that is imported and/or exported. Currently, these data are not publicly available through the
26 GHGRP due to data confidentiality reasons and hence are excluded from this analysis.

27 Facilities subject to Subpart PP of EPA’s GHGRP are required to measure CO₂ extracted or produced. More details
28 on the calculation and monitoring methods applicable to extraction and production facilities can be found under
29 Subpart PP: Suppliers of Carbon Dioxide of the regulation, Part 98.⁴¹ The number of facilities that reported data to
30 EPA’s GHGRP Subpart PP (Suppliers of Carbon Dioxide) for 2010 through 2014 is much higher (ranging from 44
31 to 48) than the number of facilities included in the Inventory for the 1990 to 2009 time period prior to the
32 availability of GHGRP data (4 facilities). The difference is largely due to the fact the 1990 to 2009 data includes
33 only CO₂ transferred to end-use applications from naturally occurring CO₂ reservoirs and excludes industrial sites.

⁴¹ See <http://www.ecfr.gov/cgi-bin/text-idx?tpl=/ecfrbrowse/Title40/40cfr98_main_02.tpl>.

1 For 2015, data from EPA’s GHGRP (Subpart PP) was unavailable for use in the current Inventory report due to data
 2 confidentiality reasons. A linear trend extrapolation was performed based on previous GHGRP reporting years
 3 (2010 to 2014) to estimate 2015 emissions. This time-series recalculation is consistent with Volume 1, Chapter 5 of
 4 the 2006 IPCC Guidelines for National Greenhouse Gas Inventories.

5 1990 through 2009

6 For 1990 through 2009, data from EPA’s GHGRP are not available. For this time period, CO₂ production data from
 7 four naturally-occurring CO₂ reservoirs were used to estimate annual CO₂ emissions. These facilities were Jackson
 8 Dome in Mississippi, Brave and West Bravo Domes in New Mexico, and McCallum Dome in Colorado. The
 9 facilities in Mississippi and New Mexico produced CO₂ for use in both EOR and in other commercial applications
 10 (e.g., chemical manufacturing, food production). The fourth facility in Colorado (McCallum Dome) produced CO₂
 11 for commercial applications only (New Mexico Bureau of Geology and Mineral Resources 2006).

12 Carbon dioxide production data and the percentage of production that was used for non-EOR applications for the
 13 Jackson Dome, Mississippi facility were obtained from Advanced Resources International (ARI 2006, 2007) for
 14 1990 to 2000, and from the Annual Reports of Denbury Resources (Denbury Resources 2002 through 2010) for
 15 2001 to 2009 (see Table 4-51). Denbury Resources reported the average CO₂ production in units of MMCF CO₂ per
 16 day for 2001 through 2009 and reported the percentage of the total average annual production that was used for
 17 EOR. Production from 1990 to 1999 was set equal to 2000 production, due to lack of publicly available production
 18 data for 1990 through 1999. Carbon dioxide production data for the Bravo Dome and West Bravo Dome were
 19 obtained from ARI for 1990 through 2009 (ARI 1990 to 2010). Data for the West Bravo Dome facility were only
 20 available for 2009. The percentage of total production that was used for non-EOR applications for the Bravo Dome
 21 and West Bravo Dome facilities for 1990 through 2009 were obtained from New Mexico Bureau of Geology and
 22 Mineral Resources (Broadhead 2003; New Mexico Bureau of Geology and Mineral Resources 2006). Production
 23 data for the McCallum Dome (Jackson County), Colorado facility were obtained from the Colorado Oil and Gas
 24 Conservation Commission (COGCC) for 1999 through 2009 (COGCC 2014). Production data for 1990 to 1998 and
 25 percentage of production used for EOR were assumed to be the same as for 1999, due to lack of publicly-available
 26 data.

27 **Table 4-51: CO₂ Production (kt CO₂) and the Percent Used for Non-EOR Applications**

Year	Jackson Dome, MS CO ₂ Production (kt) (% Non- EOR)	Bravo Dome, NM CO ₂ Production (kt) (% Non- EOR)	West Bravo Dome, NM CO ₂ Production (kt) (% Non- EOR)	McCallum Dome, CO CO ₂ Production (kt) (% Non- EOR)	Total CO ₂ Production from Extraction and Capture Facilities (kt)	% Non- EOR ^a

NA (Not available). For 2010 through 2015, the publicly available GHGRP data were aggregated at the national level.
 Facility-level data are not publicly available from EPA’s GHGRP.

Uncertainty and Time-Series Consistency – TO BE UPDATED FOR FINAL INVENTORY REPORT

There is uncertainty associated with the data reported through EPA’s GHGRP. Specifically, there is uncertainty associated with the amount of CO₂ consumed for food and beverage applications given a threshold for reporting under GHGRP applicable to those reporting under Subpart PP, in addition to the exclusion of the amount of CO₂ transferred to all other end-use categories. This latter category might include CO₂ quantities that are being used for non-EOR industrial applications such as firefighting. Second, uncertainty is associated with the exclusion of imports/exports data for CO₂ suppliers. Currently these data are not publicly available through EPA’s GHGRP and hence are excluded from this analysis.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-52. Carbon dioxide consumption CO₂ emissions for 2015 were estimated to be between 3.9 and 5.1 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 12 percent below to 13 percent above the emission estimate of 4.5 MMT CO₂ Eq.

Table 4-52: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from CO₂ Consumption (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
CO ₂ Consumption	CO ₂	4.5	3.9	5.1	-12%	+13%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Planned Improvements

EPA will continue to evaluate the potential to include additional GHGRP data on other emissive end-uses to improve accuracy and completeness of estimates for this source category. Particular attention will be made to ensuring time series consistency of the emissions estimates presented in future Inventory reports, consistent with IPCC and UNFCCC guidelines. This is required as the facility-level reporting data from EPA’s GHGRP, with the program’s initial requirements for reporting of emissions in calendar year 2010, are not available for all inventory years (i.e., 1990 through 2009) as required for this Inventory. In implementing improvements and integration of data from EPA’s GHGRP, the latest guidance from the IPCC on the use of facility-level data in national inventories will be relied upon.⁴² These improvements, in addition to updating the time-series when new data is available, are still in process and will be incorporated into future Inventory reports.

⁴² See <http://www.ipcc-nggip.iges.or.jp/meeting/pdfiles/1008_Model_and_Facility_Level_Data_Report.pdf>.

4.15 Phosphoric Acid Production (IPCC Source Category 2B10)

Phosphoric acid (H₃PO₄) is a basic raw material used in the production of phosphate-based fertilizers. Phosphoric acid production from natural phosphate rock is a source of carbon dioxide (CO₂) emissions, due to the chemical reaction of the inorganic carbon (calcium carbonate) component of the phosphate rock.

Phosphate rock is mined in Florida and North Carolina, which account for about 80 percent of total domestic output, as well as in Idaho and Utah and is used primarily as a raw material for wet-process phosphoric acid production (USGS 2016). The composition of natural phosphate rock varies depending upon the location where it is mined. Natural phosphate rock mined in the United States generally contains inorganic carbon in the form of calcium carbonate (limestone) and also may contain organic carbon. The calcium carbonate component of the phosphate rock is integral to the phosphate rock chemistry. Phosphate rock can also contain organic carbon that is physically incorporated into the mined rock but is not an integral component of the phosphate rock chemistry.

The phosphoric acid production process involves chemical reaction of the calcium phosphate (Ca₃(PO₄)₂) component of the phosphate rock with sulfuric acid (H₂SO₄) and recirculated phosphoric acid (H₃PO₄) (EFMA 2000). However, the generation of CO₂ is due to the associated limestone-sulfuric acid reaction, as shown below:

Total U.S. phosphate rock production sold or used in 2015 was 27.6 million metric tons (USGS 2016). Total imports of phosphate rock to the United States in 2015 were approximately 1.9 million metric tons (USGS 2016). Most of the imported phosphate rock (64 percent) is from Morocco, with the remaining 36 percent being from Peru (USGS 2016). All phosphate rock mining companies are vertically integrated with fertilizer plants that produce phosphoric acid located near the mines. Some additional phosphoric acid production facilities are located in Texas, Louisiana, and Mississippi that used imported phosphate rock.

Over the 1990 to 2015 period, domestic production has decreased by nearly 47 percent. Total CO₂ emissions from phosphoric acid production were 1.0 MMT CO₂ Eq. (1,007 kt CO₂) in 2015 (see Table 4-53). Domestic consumption of phosphate rock in 2015 was estimated to have decreased by approximately 2 percent over 2014 levels, owing to producers drawing from higher than average inventories and the closure of a mine in Florida. Domestic consumption also decreased because of lower phosphoric acid production (USGS 2016).

Table 4-53: CO₂ Emissions from Phosphoric Acid Production (MMT CO₂ Eq. and kt)

Year	MMT CO ₂ Eq.	kt
1990	1.5	1,529
2005	1.3	1,342
2011	1.2	1,171
2012	1.1	1,118
2013	1.1	1,149
2014	1.0	1,038
2015	1.0	1,007

Methodology

Carbon dioxide emissions from production of phosphoric acid from phosphate rock are estimated by multiplying the average amount of inorganic carbon (expressed as CO₂) contained in the natural phosphate rock as calcium carbonate by the amount of phosphate rock that is used annually to produce phosphoric acid, accounting for domestic production and net imports for consumption. The estimation methodology is as follows:

$$E_{pa} = C_{pr} \times Q_{pr}$$

1 where,

2 E_{pa} = CO₂ emissions from phosphoric acid production, metric tons
3 C_{pr} = Average amount of carbon (expressed as CO₂) in natural phosphate rock, metric ton CO₂/
4 metric ton phosphate rock
5 Q_{pr} = Quantity of phosphate rock used to produce phosphoric acid
6

7 The CO₂ emissions calculation methodology is based on the assumption that all of the inorganic C (calcium
8 carbonate) content of the phosphate rock reacts to produce CO₂ in the phosphoric acid production process and is
9 emitted with the stack gas. The methodology also assumes that none of the organic C content of the phosphate rock
10 is converted to CO₂ and that all of the organic C content remains in the phosphoric acid product.

11 From 1993 to 2004, the U.S. Geological Survey (USGS) *Mineral Yearbook: Phosphate Rock* disaggregated
12 phosphate rock mined annually in Florida and North Carolina from phosphate rock mined annually in Idaho and
13 Utah, and reported the annual amounts of phosphate rock exported and imported for consumption (see Table 4-54).
14 For the years 1990 through 1992, and 2005 through 2015, only nationally aggregated mining data was reported by
15 USGS. For the years 1990, 1991, and 1992, the breakdown of phosphate rock mined in Florida and North Carolina,
16 and the amount mined in Idaho and Utah, are approximated using average share of U.S. production in those states
17 from 1993 to 2004 data. For the years 2005 through 2015, the same approximation method is used, but the share of
18 U.S. production in those states data were obtained from the USGS commodity specialist for phosphate rock (USGS
19 2012). Data for domestic sales or consumption of phosphate rock, exports of phosphate rock (primarily from Florida
20 and North Carolina), and imports of phosphate rock for consumption for 1990 through 2015 were obtained from
21 USGS *Minerals Yearbook: Phosphate Rock* (USGS 1994 through 2015b), and from USGS *Minerals Commodity*
22 *Summaries: Phosphate Rock in 2016* (USGS 2016). From 2004 through 2015, the USGS reported no exports of
23 phosphate rock from U.S. producers (USGS 2005 through 2015b).

24 The carbonate content of phosphate rock varies depending upon where the material is mined. Composition data for
25 domestically mined and imported phosphate rock were provided by the Florida Institute of Phosphate Research
26 (FIPR 2003a). Phosphate rock mined in Florida contains approximately 1 percent inorganic C, and phosphate rock
27 imported from Morocco contains approximately 1.46 percent inorganic carbon. Calcined phosphate rock mined in
28 North Carolina and Idaho contains approximately 0.41 percent and 0.27 percent inorganic C, respectively (see Table
29 4-55).

30 Carbonate content data for phosphate rock mined in Florida are used to calculate the CO₂ emissions from
31 consumption of phosphate rock mined in Florida and North Carolina (80 percent of domestic production) and
32 carbonate content data for phosphate rock mined in Morocco are used to calculate CO₂ emissions from consumption
33 of imported phosphate rock. The CO₂ emissions calculation is based on the assumption that all of the domestic
34 production of phosphate rock is used in uncalcined form. As of 2006, the USGS noted that one phosphate rock
35 producer in Idaho produces calcined phosphate rock; however, no production data were available for this single
36 producer (USGS 2006). The USGS confirmed that no significant quantity of domestic production of phosphate rock
37 is in the calcined form (USGS 2012).

38 **Table 4-54: Phosphate Rock Domestic Consumption, Exports, and Imports (kt)**

Location/Year	1990	2005	2011	2012	2013	2014	2015

Source: FIPR (2003a).

2 **Uncertainty and Time-Series Consistency – TO BE UPDATED**

3 **FOR FINAL INVENTORY REPORT**

4 Phosphate rock production data used in the emission calculations were developed by the USGS through monthly and
 5 semiannual voluntary surveys of the active phosphate rock mines during 2015. For previous years in the time series,
 6 USGS provided the data disaggregated regionally; however, beginning in 2006, only total U.S. phosphate rock
 7 production was reported. Regional production for 2015 was estimated based on regional production data from
 8 previous years and multiplied by regionally-specific emission factors. There is uncertainty associated with the
 9 degree to which the estimated 2015 regional production data represents actual production in those regions. Total
 10 U.S. phosphate rock production data are not considered to be a significant source of uncertainty because all the
 11 domestic phosphate rock producers report their annual production to the USGS. Data for exports of phosphate rock
 12 used in the emission calculation are reported by phosphate rock producers and are not considered to be a significant
 13 source of uncertainty. Data for imports for consumption are based on international trade data collected by the U.S.
 14 Census Bureau. These U.S. government economic data are not considered to be a significant source of uncertainty.

15 An additional source of uncertainty in the calculation of CO₂ emissions from phosphoric acid production is the
 16 carbonate composition of phosphate rock; the composition of phosphate rock varies depending upon where the
 17 material is mined, and may also vary over time. The Inventory relies on one study (FIPR 2003a) of chemical
 18 composition of the phosphate rock; limited data are available beyond this study. Another source of uncertainty is the
 19 disposition of the organic carbon content of the phosphate rock. A representative of the Florida Institute of
 20 Phosphate Research (FIPR) indicated that in the phosphoric acid production process, the organic C content of the
 21 mined phosphate rock generally remains in the phosphoric acid product, which is what produces the color of the
 22 phosphoric acid product (FIPR 2003b). Organic carbon is therefore not included in the calculation of CO₂ emissions
 23 from phosphoric acid production.

24 A third source of uncertainty is the assumption that all domestically-produced phosphate rock is used in phosphoric
 25 acid production and used without first being calcined. Calcination of the phosphate rock would result in conversion
 26 of some of the organic C in the phosphate rock into CO₂. However, according to air permit information available to
 27 the public, at least one facility has calcining units permitted for operation (NCDENR 2013).

28 Finally, USGS indicated that approximately 7 percent of domestically-produced phosphate rock is used to
 29 manufacture elemental phosphorus and other phosphorus-based chemicals, rather than phosphoric acid (USGS
 30 2006). According to USGS, there is only one domestic producer of elemental phosphorus, in Idaho, and no data
 31 were available concerning the annual production of this single producer. Elemental phosphorus is produced by
 32 reducing phosphate rock with coal coke, and it is therefore assumed that 100 percent of the carbonate content of the
 33 phosphate rock will be converted to CO₂ in the elemental phosphorus production process. The calculation for CO₂
 34 emissions is based on the assumption that phosphate rock consumption, for purposes other than phosphoric acid
 35 production, results in CO₂ emissions from 100 percent of the inorganic carbon content in phosphate rock, but none
 36 from the organic carbon content.

37 The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-56. 2015 phosphoric acid
 38 production CO₂ emissions were estimated to be between 0.9 and 1.4 MMT CO₂ Eq. at the 95 percent confidence
 39 level. This indicates a range of approximately 19 percent below and 20 percent above the emission estimate of 1.1
 40 MMT CO₂ Eq.

Table 4-56: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Phosphoric Acid Production (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a (MMT CO ₂ Eq.) (%)			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Phosphoric Acid Production	CO ₂	1.1	0.9	1.4	-19%	+20%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Recalculations Discussion

Relative to the previous Inventory, the phosphate rock import data for 2011 through 2014 were revised based on updated data publicly available from USGS (USGS 2016). This revision resulted in a change in emission estimates ranging from approximately 2 to 5 percent across the time series of 2011 to 2014 compared to the previous inventory report.

Planned Improvements

EPA continues to evaluate potential improvements to the Inventory estimates for this source category, which include direct integration of EPA's Greenhouse Gas Reporting Program (GHGRP) data for 2010 through 2015 and the use of reported GHGRP data to update the inorganic C content of phosphate rock for prior years. Confidentiality of CBI is being assessed, in addition to the applicability of EPA's GHGRP data for the averaged inorganic C content data (by region) from 2010 through 2015 to inform estimates in prior years in the required time series (i.e., 1990 through 2009). In implementing improvements and integration of data from EPA's GHGRP, the latest guidance from the IPCC on the use of facility-level data in national inventories will be relied upon.⁴³ This planned improvement is still in development by EPA and have not been implemented into the current inventory report.

4.16 Iron and Steel Production (IPCC Source Category 2C1) and Metallurgical Coke Production

Iron and steel production is a multi-step process that generates process-related emissions of carbon dioxide (CO₂) and methane (CH₄) as raw materials are refined into iron and then transformed into crude steel. Emissions from conventional fuels (e.g., natural gas, fuel oil) consumed for energy purposes during the production of iron and steel are accounted for in the Energy chapter.

Iron and steel production includes six distinct production processes: coke production, sinter production, direct reduced iron (DRI) production, pig iron production, electric arc furnace (EAF) steel production, and basic oxygen furnace (BOF) steel production. The number of production processes at a particular plant is dependent upon the specific plant configuration. In addition to the production processes mentioned above, CO₂ is also generated at iron and steel mills through the consumption of process byproducts (e.g., blast furnace gas, coke oven gas) used for

⁴³ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

various purposes including heating, annealing, and electricity generation. Process byproducts sold for use as synthetic natural gas are deducted and reported in the Energy chapter. In general, CO₂ emissions are generated in these production processes through the reduction and consumption of various carbon-containing inputs (e.g., ore, scrap, flux, coke byproducts). In addition, fugitive CH₄ emissions can also be generated from these processes but also sinter, direct iron and pellet production.

Currently, there are between 15 and 20 integrated iron and steel steelmaking facilities that utilize BOFs to refine and produce steel from iron and more than 100 steelmaking facilities that utilize EAFs to produce steel primarily from recycled ferrous scrap. In addition, there are 18 cokemaking facilities, of which 7 facilities are co-located with integrated iron and steel facilities. Slightly more than 62 percent of the raw steel produced in the United States is produced in one of seven states: Alabama, Arkansas, Indiana, Kentucky, Mississippi, Ohio, and Tennessee (AISI 2016a).

Total production of crude steel in the United States between 2000 and 2008 ranged from a low of 99,320,000 tons to a high of 109,880,000 tons (2001 and 2004, respectively). Due to the decrease in demand caused by the global economic downturn (particularly from the automotive industry), crude steel production in the United States sharply decreased to 65,459,000 tons in 2009. In 2010, crude steel production rebounded to 88,731,000 tons as economic conditions improved and then continued to increase to 95,237,000 tons in 2011 and 97,769,000 tons in 2012; crude steel production slightly decreased to 95,766,000 tons in 2013 and then slightly increased to 97,195,000 tons in 2014 (AISI 2016a); crude steel production decreased to 86,912,000 tons in 2015, a decrease of roughly 10 percent from 2014 levels. The United States was the fourth largest producer of raw steel in the world, behind China, Japan and India, accounting for approximately 4.9 percent of world production in 2015 (AISI 2016a).

The majority of CO₂ emissions from the iron and steel production process come from the use of coke in the production of pig iron and from the consumption of other process byproducts, with lesser amounts emitted from the use of flux and from the removal of carbon from pig iron used to produce steel.

According to the *2006 IPCC Guidelines*, the production of metallurgical coke from coking coal is considered to be an energy use of fossil fuel and the use of coke in iron and steel production is considered to be an industrial process source. Therefore, the *2006 IPCC Guidelines* suggest that emissions from the production of metallurgical coke should be reported separately in the Energy sector, while emissions from coke consumption in iron and steel production should be reported in the Industrial Processes and Product Use sector. However, the approaches and emission estimates for both metallurgical coke production and iron and steel production are both presented here because much of the relevant activity data is used to estimate emissions from both metallurgical coke production and iron and steel production. For example, some byproducts (e.g., coke oven gas) of the metallurgical coke production process are consumed during iron and steel production, and some byproducts of the iron and steel production process (e.g., blast furnace gas) are consumed during metallurgical coke production. Emissions associated with the consumption of these byproducts are attributed at the point of consumption. Emissions associated with the use of conventional fuels (e.g., natural gas, fuel oil) for electricity generation, heating and annealing, or other miscellaneous purposes downstream of the iron and steelmaking furnaces are reported in the Energy chapter.

Metallurgical Coke Production

Emissions of CO₂ from metallurgical coke production in 2015 were 2.8 MMT CO₂ Eq. (2,839 kt CO₂) (see Table 4-57 and Table 4-58). Emissions increased in 2015 from 2014 levels and have increased overall since 1990. In the previous inventory, 2014 domestic coke production data were not published, so 2013 data was used as a proxy. In this report, domestic coke production data for 2015 was available and so 2014 data were not used as proxy for 2015, differing from the previous inventory report. 2014 published domestic coke production data were also updated. Coke production in 2015 was 34 percent lower than in 2000 and 50 percent below 1990. Overall, emissions from metallurgical coke production have increased by 13 percent (0.3 MMT CO₂ Eq.) from 1990 to 2015.

Table 4-57: CO₂ Emissions from Metallurgical Coke Production (MMT CO₂ Eq.)

Gas	1990	2005	2011	2012	2013	2014	2015
CO ₂	2.5	2.0	1.4	0.5	1.8	2.0	2.8
Total	2.5	2.0	1.4	0.5	1.8	2.0	2.8

1 **Table 4-58: CO₂ Emissions from Metallurgical Coke Production (kt)**

Gas	1990	2005	2011	2012	2013	2014	2015
CO ₂	2,503	2,044	1,426	543	1,824	2,014	2,839

3
4 **Iron and Steel Production**

5 Emissions of CO₂ and CH₄ from iron and steel production in 2015 were 45.1 MMT CO₂ Eq. (45,075 kt) and 0.0086
6 MMT CO₂ Eq. (0.3 kt), respectively (see Table 4-59 through Table 4-62), totaling approximately 45.1 MMT CO₂
7 Eq. Emissions decreased in 2015 and have decreased overall since 1990 due to restructuring of the industry,
8 technological improvements, and increased scrap steel utilization. Carbon dioxide emission estimates include
9 emissions from the consumption of carbonaceous materials in the blast furnace, EAF, and BOF, as well as blast
10 furnace gas and coke oven gas consumption for other activities at the steel mill.

11 In 2015, domestic production of pig iron decreased by 13 percent from 2014 levels. Overall, domestic pig iron
12 production has declined since the 1990s. Pig iron production in 2015 was 47 percent lower than in 2000 and 49
13 percent below 1990. Carbon dioxide emissions from steel production have increased by 2 percent (0.1 MMT CO₂
14 Eq.) since 1990, while overall CO₂ emissions from iron and steel production have declined by 54 percent (52.1
15 MMT CO₂ Eq.) from 1990 to 2015.

16 **Table 4-59: CO₂ Emissions from Iron and Steel Production (MMT CO₂ Eq.)**

Source/Activity Data	1990	2005	2011	2012	2013	2014	2015
Sinter Production	2.4	1.7	1.2	1.2	1.1	1.1	1.0
Iron Production	45.6	17.5	18.4	10.9	11.9	18.6	11.7

2 Methodology

3 Emission estimates presented in this chapter are largely based on Tier 2 methodologies provided by the *2006 IPCC*
 4 *Guidelines*. These Tier 2 methodologies call for a mass balance accounting of the carbonaceous inputs and outputs
 5 during the iron and steel production process and the metallurgical coke production process. Tier 1 methods are used
 6 for certain iron and steel production processes (i.e., sinter production, pellet production and DRI production) for
 7 which available data are insufficient for utilizing a Tier 2 method.

8 The Tier 2 methodology equation is as follows:

$$9 \quad E_{CO_2} = \left[\sum_a (Q_a \times C_a) - \sum_b (Q_b \times C_b) \right] \times \frac{44}{12}$$

10 where,

11	E_{CO_2}	=	Emissions from coke, pig iron, EAF steel, or BOF steel production, metric tons
12	a	=	Input material a
13	b	=	Output material b
14	Q_a	=	Quantity of input material a , metric tons
15	C_a	=	Carbon content of input material a , metric tons C/metric ton material
16	Q_b	=	Quantity of output material b , metric tons
17	C_b	=	Carbon content of output material b , metric tons C/metric ton material
18	$44/12$	=	Stoichiometric ratio of CO ₂ to C

20 The Tier 1 methodology equations are as follows:

$$21 \quad E_{s,p} = Q_s \times EF_{s,p}$$

$$22 \quad E_{d,CO_2} = Q_d \times EF_{d,CO_2}$$

$$23 \quad E_{p,CO_2} = Q_p \times EF_{p,CO_2}$$

24 where,

25	$E_{s,p}$	=	Emissions from sinter production process for pollutant p (CO ₂ or CH ₄), metric ton
26	Q_s	=	Quantity of sinter produced, metric tons
27	$EF_{s,p}$	=	Emission factor for pollutant p (CO ₂ or CH ₄), metric ton p /metric ton sinter
28	E_{d,CO_2}	=	Emissions from DRI production process for CO ₂ , metric ton
29	Q_d	=	Quantity of DRI produced, metric tons
30	EF_{d,CO_2}	=	Emission factor for CO ₂ , metric ton CO ₂ /metric ton DRI
31	Q_p	=	Quantity of pellets produced, metric tons
32	EF_{p,CO_2}	=	Emission factor for CO ₂ , metric ton CO ₂ /metric ton pellets produced

34 Metallurgical Coke Production

35 Coking coal is used to manufacture metallurgical coke that is used primarily as a reducing agent in the production of
 36 iron and steel, but is also used in the production of other metals including zinc and lead (see *Zinc Production* and
 37 *Lead Production* sections of this chapter). Emissions associated with producing metallurgical coke from coking coal
 38 are estimated and reported separately from emissions that result from the iron and steel production process. To
 39 estimate emissions from metallurgical coke production, a Tier 2 method provided by the *2006 IPCC Guidelines* was
 40 utilized. The amount of carbon contained in materials produced during the metallurgical coke production process

(i.e., coke, coke breeze, coke oven gas, and coal tar) is deducted from the amount of carbon contained in materials consumed during the metallurgical coke production process (i.e., natural gas, blast furnace gas, and coking coal). Light oil, which is produced during the metallurgical coke production process, is excluded from the deductions due to data limitations. The amount of carbon contained in these materials is calculated by multiplying the material-specific carbon content by the amount of material consumed or produced (see Table 4-63). The amount of coal tar produced was approximated using a production factor of 0.03 tons of coal tar per ton of coking coal consumed. The amount of coke breeze produced was approximated using a production factor of 0.075 tons of coke breeze per ton of coking coal consumed (AISI 2008; DOE 2000). Data on the consumption of carbonaceous materials (other than coking coal) as well as coke oven gas production were available for integrated steel mills only (i.e., steel mills with co-located coke plants). Therefore, carbonaceous material (other than coking coal) consumption and coke oven gas production were excluded from emission estimates for merchant coke plants. Carbon contained in coke oven gas used for coke-oven underfiring was not included in the deductions to avoid double-counting.

Table 4-63: Material Carbon Contents for Metallurgical Coke Production

Material	kg C/kg
Coal Tar	0.62
Coke	0.83
Coke Breeze	0.83
Coking Coal	0.73
Material	kg C/GJ
Coke Oven Gas	12.1
Blast Furnace Gas	70.8

Source: IPCC (2006), Table 4.3. Coke Oven Gas and Blast Furnace Gas, Table 1.3.

Although the 2006 IPCC Guidelines provide a Tier 1 CH₄ emission factor for metallurgical coke production (i.e., 0.1 g CH₄ per metric ton of coke production), it is not appropriate to use because CO₂ emissions were estimated using the Tier 2 mass balance methodology. The mass balance methodology makes a basic assumption that all carbon that enters the metallurgical coke production process either exits the process as part of a carbon-containing output or as CO₂ emissions. This is consistent with a preliminary assessment of aggregated facility-level greenhouse gas CH₄ emissions reported by coke production facilities under EPA's GHGRP. The assessment indicates that CH₄ emissions from coke production are below 500 kt or 0.05 percent of total national emissions. Pending resources and significance, EPA will assess the possibility of including these emissions in future reports to enhance completeness and has not incorporated these emissions into this report.

Data relating to the mass of coking coal consumed at metallurgical coke plants and the mass of metallurgical coke produced at coke plants were taken from the Energy Information Administration (EIA), *Quarterly Coal Report: October through December* (EIA 1998 through 2016a) (see Table 4-64). Data on the volume of natural gas consumption, blast furnace gas consumption, and coke oven gas production for metallurgical coke production at integrated steel mills were obtained from the American Iron and Steel Institute (AISI), *Annual Statistical Report* (AISI 2004 through 2016a) and through personal communications with AISI (AISI 2008) (see Table 4-65). The factor for the quantity of coal tar produced per ton of coking coal consumed was provided by AISI (AISI 2008). The factor for the quantity of coke breeze produced per ton of coking coal consumed was obtained through Table 2-1 of the report *Energy and Environmental Profile of the U.S. Iron and Steel Industry* (DOE 2000). Data on natural gas consumption and coke oven gas production at merchant coke plants were not available and were excluded from the emission estimate. Carbon contents for coking coal, metallurgical coke, coal tar, coke oven gas, and blast furnace gas were provided by the 2006 IPCC Guidelines. The C content for coke breeze was assumed to equal the C content of coke.

Table 4-64: Production and Consumption Data for the Calculation of CO₂ and CH₄ Emissions from Metallurgical Coke Production (Thousand Metric Tons)

Source/Activity Data	1990	2005	2011	2012	2013	2014	2015
Metallurgical Coke Production

3 Iron and Steel Production

4 Emissions of CO₂ from sinter production, direct reduced iron production and pellet production were estimated by
5 multiplying total national sinter production and the total national direct reduced iron production by Tier 1 CO₂
6 emission factors (see Table 4-66). Because estimates of sinter production, direct reduced iron production and pellet
7 production were not available, production was assumed to equal consumption.

8 **Table 4-66: CO₂ Emission Factors for Sinter Production, Direct Reduced Iron Production and**
9 **Pellet Production**

Material Produced	Metric Ton CO ₂ /Metric Ton
Sinter	0.2
Direct Reduced Iron	0.7
Pellet Production	0.03

Source: IPCC (2006), Table 4.1.

10 To estimate emissions from pig iron production in the blast furnace, the amount of carbon contained in the produced
11 pig iron and blast furnace gas were deducted from the amount of carbon contained in inputs (i.e., metallurgical coke,
12 sinter, natural ore, pellets, natural gas, fuel oil, coke oven gas, and direct coal injection). The carbon contained in the
13 pig iron, blast furnace gas, and blast furnace inputs was estimated by multiplying the material-specific C content by
14 each material type (see Table 4-67). Carbon in blast furnace gas used to pre-heat the blast furnace air is combusted
15 to form CO₂ during this process. Carbon contained in blast furnace gas used as a blast furnace input was not
16 included in the deductions to avoid double-counting.

17 Emissions from steel production in EAFs were estimated by deducting the carbon contained in the steel produced
18 from the carbon contained in the EAF anode, charge carbon, and scrap steel added to the EAF. Small amounts of
19 carbon from direct reduced iron, pig iron, and flux additions to the EAFs were also included in the EAF calculation.
20 For BOFs, estimates of carbon contained in BOF steel were deducted from C contained in inputs such as natural gas,
21 coke oven gas, fluxes, and pig iron. In each case, the carbon was calculated by multiplying material-specific carbon
22 contents by each material type (see Table 4-67). For EAFs, the amount of EAF anode consumed was approximated
23 by multiplying total EAF steel production by the amount of EAF anode consumed per metric ton of steel produced
24 (0.002 metric tons EAF anode per metric ton steel produced [AISI 2008]). The amount of flux (e.g., limestone and
25 dolomite) used during steel manufacture was deducted from the “Other Process Uses of Carbonates” source category
26 (IPCC Source Category 2A4) to avoid double-counting.

27 Carbon dioxide emissions from the consumption of blast furnace gas and coke oven gas for other activities occurring
28 at the steel mill were estimated by multiplying the amount of these materials consumed for these purposes by the
29 material-specific carbon content (see Table 4-67).

30 Carbon dioxide emissions associated with the sinter production, direct reduced iron production, pig iron production,
31 steel production, and other steel mill activities were summed to calculate the total CO₂ emissions from iron and steel
32 production (see Table 4-59 and Table 4-60).

2 The production process for sinter results in fugitive emissions of CH₄, which are emitted via leaks in the production
 3 equipment, rather than through the emission stacks or vents of the production plants. The fugitive emissions were
 4 calculated by applying Tier 1 emission factors taken from the *2006 IPCC Guidelines* for sinter production (see Table
 5 4-68). Although the *1995 IPCC Guidelines* (IPCC/UNEP/OECD/IEA 1995) provide a Tier 1 CH₄ emission factor
 6 for pig iron production, it is not appropriate to use because CO₂ emissions were estimated using the Tier 2 mass
 7 balance methodology. The mass balance methodology makes a basic assumption that all carbon that enters the pig
 8 iron production process either exits the process as part of a carbon-containing output or as CO₂ emissions; the
 9 estimation of CH₄ emissions is precluded. A preliminary analysis of facility-level emissions reported during iron
 10 production further supports this assumption and indicates that CH₄ emissions are below 500 kt CO₂ Eq. and well
 11 below 0.05 percent of total national emissions. The production of direct reduced iron also results in emissions of
 12 CH₄ through the consumption of fossil fuels (e.g., natural gas, etc.); however, these emission estimates are excluded
 13 due to data limitations. Pending further analysis and resources, EPA may include these emissions in future reports to
 14 enhance completeness. EPA is still assessing the possibility of including these emissions in future reports and have
 15 not included this data into the current report.

16 **Table 4-68: CH₄ Emission Factors for Sinter and Pig Iron Production**

Material Produced	Factor	Unit
Sinter	0.07	kg CH ₄ /metric ton

Source: IPCC (2006), Table 4.2.

17 Sinter consumption and pellet consumption data for 1990 through 2015 were obtained from AISI's *Annual*
 18 *Statistical Report* (AISI 2004 through 2016a) and through personal communications with AISI (AISI 2008) (see
 19 Table 4-69). In general, direct reduced iron (DRI) consumption data were obtained from the U.S. Geological Survey
 20 (USGS) *Minerals Yearbook – Iron and Steel Scrap* (USGS 1991 through 2015) and personal communication with
 21 the USGS Iron and Steel Commodity Specialist (Fenton 2015). However, data for DRI consumed in EAFs were not
 22 available for the years 1990 and 1991. EAF DRI consumption in 1990 and 1991 was calculated by multiplying the
 23 total DRI consumption for all furnaces by the EAF share of total DRI consumption in 1992. Also, data for DRI
 24 consumed in BOFs were not available for the years 1990 through 1993. BOF DRI consumption in 1990 through
 25 1993 was calculated by multiplying the total DRI consumption for all furnaces (excluding EAFs and cupola) by the
 26 BOF share of total DRI consumption (excluding EAFs and cupola) in 1994.

27 The Tier 1 CO₂ emission factors for sinter production, direct reduced iron production and pellet production were
 28 obtained through the *2006 IPCC Guidelines* (IPCC 2006). Time series data for pig iron production, coke, natural
 29 gas, fuel oil, sinter, and pellets consumed in the blast furnace; pig iron production; and blast furnace gas produced at
 30 the iron and steel mill and used in the metallurgical coke ovens and other steel mill activities were obtained from
 31 AISI's *Annual Statistical Report* (AISI 2004 through 2016a) and through personal communications with AISI (AISI
 32 2008) (see Table 4-69 and Table 4-70).

33 Data for EAF steel production, flux, EAF charge carbon, and natural gas consumption were obtained from AISI's
 34 *Annual Statistical Report* (AISI 2004 through 2016a) and through personal communications with AISI (AISI 2006

through 2016b and AISI 2008). The factor for the quantity of EAF anode consumed per ton of EAF steel produced was provided by AISI (AISI 2008). Data for BOF steel production, flux, natural gas, natural ore, pellet, sinter consumption as well as BOF steel production were obtained from AISI's *Annual Statistical Report* (AISI 2004 through 2016a) and through personal communications with AISI (AISI 2008). Data for EAF and BOF scrap steel, pig iron, and DRI consumption were obtained from the USGS *Minerals Yearbook – Iron and Steel Scrap* (USGS 1991 through 2015). Data on coke oven gas and blast furnace gas consumed at the iron and steel mill (other than in the EAF, BOF, or blast furnace) were obtained from AISI's *Annual Statistical Report* (AISI 2004 through 2016a) and through personal communications with AISI (AISI 2008).

Data on blast furnace gas and coke oven gas sold for use as synthetic natural gas were obtained from EIA's *Natural Gas Annual* (EIA 2016b). Carbon contents for direct reduced iron, EAF carbon electrodes, EAF charge carbon, limestone, dolomite, pig iron, and steel were provided by the *2006 IPCC Guidelines*. The carbon contents for natural gas, fuel oil, and direct injection coal were obtained from EIA (EIA 2016c) and EPA (EPA 2010). Heat contents for fuel oil and direct injection coal were obtained from EIA (EIA 1992, 2011); natural gas heat content was obtained from Table 37 of AISI's *Annual Statistical Report* (AISI 2004 through 2016a). Heat contents for coke oven gas and blast furnace gas were provided in Table 37 of AISI's *Annual Statistical Report* (AISI 2004 through 2016a) and confirmed by AISI staff (Carroll 2016).

Table 4-69: Production and Consumption Data for the Calculation of CO₂ and CH₄ Emissions from Iron and Steel Production (Thousand Metric Tons)

Source/Activity Data	1990	2005	2011	2012	2013	2014	2015

3 **Uncertainty and Time-Series Consistency – TO BE UPDATED** 4 **FOR FINAL INVENTORY REPORT**

5 The estimates of CO₂ emissions from metallurgical coke production are based on material production and
 6 consumption data and average carbon contents. Uncertainty is associated with the total U.S. coking coal
 7 consumption, total U.S. coke production and materials consumed during this process. Data for coking coal
 8 consumption and metallurgical coke production are from different data sources (EIA) than data for other
 9 carbonaceous materials consumed at coke plants (AISI), which does not include data for merchant coke plants.
 10 There is uncertainty associated with the fact that coal tar and coke breeze production were estimated based on coke
 11 production because coal tar and coke breeze production data were not available. Since merchant coke plant data is
 12 not included in the estimate of other carbonaceous materials consumed at coke plants, the mass balance equation for
 13 CO₂ from metallurgical coke production cannot be reasonably completed. Therefore, for the purpose of this analysis,
 14 uncertainty parameters are applied to primary data inputs to the calculation (i.e., coking coal consumption and
 15 metallurgical coke production) only.

16 The estimates of CO₂ emissions from iron and steel production are based on material production and consumption
 17 data and average C contents. Current estimates include estimates from pellet consumption, but exclude emissions
 18 from pellet production. For the Final draft of this Inventory report (i.e., 1990 through 2015), pellet production will
 19 be included in emissions estimates. There is uncertainty associated with the assumption that pellet production, direct
 20 reduced iron and sinter consumption are equal to production. There is uncertainty with the representativeness of the
 21 associated IPCC default emission factors. There is uncertainty associated with the assumption that all coal used for
 22 purposes other than coking coal is for direct injection coal; some of this coal may be used for electricity generation.
 23 There is also uncertainty associated with the C contents for pellets, sinter, and natural ore, which are assumed to
 24 equal the C contents of direct reduced iron, when consumed in the blast furnace. For EAF steel production, there is
 25 uncertainty associated with the amount of EAF anode and charge carbon consumed due to inconsistent data
 26 throughout the time series. Also for EAF steel production, there is uncertainty associated with the assumption that
 27 100 percent of the natural gas attributed to “steelmaking furnaces” by AISI is process-related and nothing is
 28 combusted for energy purposes. Uncertainty is also associated with the use of process gases such as blast furnace
 29 gas and coke oven gas. Data are not available to differentiate between the use of these gases for processes at the
 30 steel mill versus for energy generation (i.e., electricity and steam generation); therefore, all consumption is attributed

to iron and steel production. These data and carbon contents produce a relatively accurate estimate of CO₂ emissions. However, there are uncertainties associated with each.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-71 for metallurgical coke production and iron and steel production. Total CO₂ emissions from metallurgical coke production and iron and steel production for 2015 were estimated to be between 47.2 and 63.6 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 15 percent below and 15 percent above the emission estimate of 55.4 MMT CO₂ Eq. Total CH₄ emissions from metallurgical coke production and iron and steel production for 2015 were estimated to be between 0.008 and 0.01 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 19 percent below and 19 percent above the emission estimate of 0.009 MMT CO₂ Eq.

Table 4-71: Approach 2 Quantitative Uncertainty Estimates for CO₂ and CH₄ Emissions from Iron and Steel Production and Metallurgical Coke Production (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Metallurgical Coke & Iron and Steel Production	CO ₂	55.4	47.2	63.6	-15%	+15%
Metallurgical Coke & Iron and Steel Production	CH ₄	+	+	+	-19%	+19%

+ Does not exceed 0.05 MMT CO₂ Eq.

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Recalculations Discussion

Updated data was obtained for 2014 direct reduced iron production (USGS 2015), 2014 process inputs for metallurgical coke production, outputs of U.S. metallurgical coke production and direct reduced iron consumption for BOF steel production (EIA 2016a). These revisions resulted in an increase of 2014 CO₂ emissions estimates from metallurgical coke production and 2014 CO₂ emissions estimates from iron and steel production by 4 percent each compared to the previous inventory report.

Planned Improvements

Future improvements involve improving activity data and emission factor sources for estimating CO₂ and CH₄ emissions from pellet production. The EPA has identified a potential activity data source for national-level pellet production and plans to update estimates based on this data for the final draft of this year's inventory report (i.e., 1990 through 2015), pending schedule and resources. The EPA has reported pellet production activity data into Table 4-69 of the methodology section, as shown above, but has not incorporated that data into emissions estimates. EPA will also evaluate and analyze data reported under EPA's GHGRP to improve the emission estimates for this and other Iron and Steel Production process categories. Particular attention will be made to ensure time series consistency of the emissions estimates presented in future Inventory reports, consistent with IPCC and UNFCCC guidelines. This is required as the facility-level reporting data from EPA's GHGRP, with the program's initial requirements for reporting of emissions in calendar year 2010, are not available for all inventory years (i.e., 1990 through 2009) as required for this Inventory. In implementing improvements and integration of data from EPA's GHGRP, the latest guidance from the IPCC on the use of facility-level data in national inventories will be relied upon.⁴⁴

⁴⁴ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

Additional improvements include accounting for emission estimates for the production of metallurgical coke to the Energy chapter as well as identifying the amount of carbonaceous materials, other than coking coal, consumed at merchant coke plants. Other potential improvements include identifying the amount of coal used for direct injection and the amount of coke breeze, coal tar, and light oil produced during coke production. Efforts will also be made to identify information to better characterize emissions from the use of process gases and fuels within the Energy and Industrial Processes and Product Use chapters. This planned improvement is still in development and is not included in this current inventory report.

4.17 Ferroalloy Production (IPCC Source Category 2C2)

Carbon dioxide (CO₂) and methane (CH₄) are emitted from the production of several ferroalloys. Ferroalloys are composites of iron (Fe) and other elements such as silicon (Si), manganese (Mn), and chromium (Cr). Emissions from fuels consumed for energy purposes during the production of ferroalloys are accounted for in the Energy chapter. Emissions from the production of two types of ferrosilicon (25 to 55 percent and 56 to 95 percent silicon), silicon metal (96 to 99 percent silicon), and miscellaneous alloys (32 to 65 percent silicon) have been calculated. Emissions from the production of ferrochromium and ferromanganese are not included here because of the small number of manufacturers of these materials in the United States, and therefore, government information disclosure rules prevent the publication of production data for these production facilities.

Similar to emissions from the production of iron and steel, CO₂ is emitted when metallurgical coke is oxidized during a high-temperature reaction with iron and the selected alloying element. Due to the strong reducing environment, CO is initially produced, and eventually oxidized to CO₂. A representative reaction equation for the production of 50 percent ferrosilicon (FeSi) is given below:

While most of the carbon contained in the process materials is released to the atmosphere as CO₂, a percentage is also released as CH₄ and other volatiles. The amount of CH₄ that is released is dependent on furnace efficiency, operation technique, and control technology.

When incorporated in alloy steels, ferroalloys are used to alter the material properties of the steel. Ferroalloys are used primarily by the iron and steel industry, and production trends closely follow that of the iron and steel industry. Twelve companies in the United States produce ferroalloys (USGS 2016a).

Emissions of CO₂ from ferroalloy production in 2015 were 2.0 MMT CO₂ Eq. (1,960 kt CO₂) (see Table 4-72 and Table 4-73), which is a 9 percent reduction since 1990. Emissions of CH₄ from ferroalloy production in 2015 were 0.01 MMT CO₂ Eq. (0.5 kt CH₄), which is a 19 percent decrease since 1990.

Table 4-72: CO₂ and CH₄ Emissions from Ferroalloy Production (MMT CO₂ Eq.)

Gas	1990	2005	2011	2012	2013	2014	2015
CO ₂	2.2	1.4	1.7	1.9	1.8	1.9	2.0
CH ₄	+	+	+	+	+	+	+
Total	2.2	1.4	1.7	1.9	1.8	1.9	2.0

+ Does not exceed 0.05 MMT CO₂ Eq.

1 **Table 4-73: CO₂ and CH₄ Emissions from Ferroalloy Production (kt)**

+ Does not exceed 0.5 kt.

2 Methodology

3 Emissions of CO₂ and CH₄ from ferroalloy production were calculated⁴⁵ using a Tier 1 method from the 2006 IPCC
 4 *Guidelines* by multiplying annual ferroalloy production by material-specific default emission factors provided by
 5 IPCC (IPCC 2006). The Tier 1 equations for CO₂ and CH₄ emissions are as follows:

$$E_{CO_2} = \sum_i (MP_i \times EF_i)$$

8 where,

9 E_{CO₂} = CO₂ emissions, metric tons
 10 MP_i = Production of ferroalloy type *i*, metric tons
 11 EF_i = Generic emission factor for ferroalloy type *i*, metric tons CO₂/metric ton specific
 12 ferroalloy product
 13
 14

$$E_{CH_4} = \sum_i (MP_i \times EF_i)$$

16 where,

17 E_{CH₄} = CH₄ emissions, kg
 18 MP_i = Production of ferroalloy type *i*, metric tons
 19 EF_i = Generic emission factor for ferroalloy type *i*, kg CH₄/metric ton specific ferroalloy
 20 product

21 Default emission factors were used because country-specific emission factors are not currently available. The
 22 following emission factors were used to develop annual CO₂ and CH₄ estimates:

- 23 • Ferrosilicon, 25 to 55 percent Si and Miscellaneous Alloys, 32 to 65 percent Si – 2.5 metric tons
 24 CO₂/metric ton of alloy produced; 1.0 kg CH₄/metric ton of alloy produced.
- 25 • Ferrosilicon, 56 to 95 percent Si – 4.0 metric tons CO₂/metric ton alloy produced; 1.0 kg CH₄/metric ton of
 26 alloy produced.
- 27 • Silicon Metal – 5.0 metric tons CO₂/metric ton metal produced; 1.2 kg CH₄/metric ton metal produced.

28 It was assumed that 100 percent of the ferroalloy production was produced using petroleum coke in an electric arc
 29 furnace process (IPCC 2006), although some ferroalloys may have been produced with coking coal, wood, other
 30 biomass, or graphite carbon inputs. The amount of petroleum coke consumed in ferroalloy production was
 31 calculated assuming that the petroleum coke used is 90 percent carbon (C) and 10 percent inert material (Onder and
 32 Bagdoyan 1993).

33 Ferroalloy production data for 1990 through 2015 (see Table 4-74) were obtained from the U.S. Geological Survey
 34 (USGS) through the *Minerals Yearbook: Silicon* (USGS 1996 through 2013) and the *Mineral Industry Surveys*:

⁴⁵ EPA has not integrated aggregated facility-level GHGRP information to inform these estimates. The aggregated information (e.g., activity data and emissions) associated with production of ferroalloys did not meet criteria to shield underlying confidential business information (CBI) from public disclosure.

1 *Silicon* (USGS 2014, 2015b, 2016b). The following data were available from the USGS publications for the time-
 2 series:

- 3 • Ferrosilicon, 25 to 55 percent Si: Annual production data were available from 1990 through 2010.
- 4 • Ferrosilicon, 56 to 95 percent Si: Annual production data were available from 1990 through 2010.
- 5 • Silicon Metal: Annual production data were available from 1990 through 2005. The production data for
 6 2005 were used as proxy for 2006 through 2010.
- 7 • Miscellaneous Alloys, 32 to 65 percent Si: Annual production data were available from 1990 through 1999.
 8 Starting 2000, USGS reported miscellaneous alloys and ferrosilicon containing 25 to 55 percent silicon as a
 9 single category.

10 Starting with the 2011 publication, USGS reported all the ferroalloy production data as a single category (i.e., Total
 11 Silicon Materials Production). This is due to the small number of ferroalloy manufacturers in the United States and
 12 government information disclosure rules. Ferroalloy product shares developed from the 2010 production data (i.e.,
 13 ferroalloy product production/total ferroalloy production) were used with the total silicon materials production
 14 quantity to estimate the production quantity by ferroalloy product type for 2011 through 2015 (USGS 2013, 2014,
 15 2015b, 2016b).

16 **Table 4-74: Production of Ferroalloys (Metric Tons)**

Year	Ferrosilicon 25%-55%	Ferrosilicon 56%-95%	Silicon Metal	Misc. Alloys 32-65%
1990	321,385	109,566	145,744	72,442
2005	123,000	86,100	148,000	NA
2011	159,667	140,883	154,450	NA
2012	175,108	154,507	169,385	NA
2013	164,229	144,908	158,862	NA
2014	176,161	155,436	170,404	NA
2015	180,372	159,151	174,477	NA

NA - Not Available for product type, aggregated along with ferrosilicon (25-55% Si)

17 **Uncertainty and Time-Series Consistency – TO BE UPDATED** 18 **FOR FINAL INVENTORY REPORT**

19 Annual ferroalloy production was reported by the USGS in three broad categories until the 2010 publication:
 20 ferroalloys containing 25 to 55 percent silicon (including miscellaneous alloys), ferroalloys containing 56 to 95
 21 percent silicon, and silicon metal (through 2005 only, 2005 value used as proxy for 2005 through 2010). Starting
 22 with the *2011 Minerals Yearbook*, USGS started reporting all the ferroalloy production under a single category: total
 23 silicon materials production. The total silicon materials quantity was allocated across the three categories based on
 24 the 2010 production shares for the three categories. Refer to the Methodology section for further details.
 25 Additionally, production data for silvery pig iron (alloys containing less than 25 percent silicon) are not reported by
 26 the USGS to avoid disclosing proprietary company data. Emissions from this production category, therefore, were
 27 not estimated.

28 Also, some ferroalloys may be produced using wood or other biomass as a primary or secondary carbon source
 29 (carbonaceous reductants), however information and data regarding these practices were not available. Emissions
 30 from ferroalloys produced with wood or other biomass would not be counted under this source because wood-based
 31 carbon is of biogenic origin.⁴⁶ Even though emissions from ferroalloys produced with coking coal or graphite inputs
 32 would be counted in national trends, they may be generated with varying amounts of CO₂ per unit of ferroalloy
 33 produced. The most accurate method for these estimates would be to base calculations on the amount of reducing

⁴⁶ Emissions and sinks of biogenic carbon are accounted for in the Land Use, Land-Use Change, and Forestry chapter.

agent used in the process, rather than the amount of ferroalloys produced. These data, however, were not available, and are also often considered confidential business information.

Emissions of CH₄ from ferroalloy production will vary depending on furnace specifics, such as type, operation technique, and control technology. Higher heating temperatures and techniques such as sprinkle charging will reduce CH₄ emissions; however, specific furnace information was not available or included in the CH₄ emission estimates.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-75. Ferroalloy production CO₂ emissions from 2015 were estimated to be between 1.7 and 2.1 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 12 percent below and 12 percent above the emission estimate of 1.9 MMT CO₂ Eq. Ferroalloy production CH₄ emissions were estimated to be between a range of approximately 12 percent below and 12 percent above the emission estimate of 0.01 MMT CO₂ Eq.

Table 4-75: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Ferroalloy Production (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Ferroalloy Production	CO ₂	1.9	1.7	2.1	-12%	+12%
Ferroalloy Production	CH ₄	+	+	+	-12%	+12%

+ Does not exceed 0.05 MMT CO₂ Eq.

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Planned Improvements

Pending available resources and prioritization of improvements for more significant sources, EPA will continue to evaluate and analyze data reported under EPA's GHGRP that would be useful to improve the emission estimates and category-specific QC procedures for the Ferroalloy Production source category. Given the small number of facilities, particular attention will be made to ensure time series consistency of the emissions estimates presented in future Inventory reports, consistent with IPCC and UNFCCC guidelines. This is required as the facility-level reporting data from EPA's GHGRP, with the program's initial requirements for reporting of emissions in calendar year 2010, are not available for all inventory years (i.e., 1990 through 2009) as required for this Inventory. In implementing improvements and integration of data from EPA's GHGRP, the latest guidance from the IPCC on the use of facility-level data in national inventories will be relied upon.⁴⁷ EPA is still assessing the possibility of incorporating this planned improvement into the annual inventory report and has not included these data sets into the current inventory report.

4.18 Aluminum Production (IPCC Source Category 2C3)

Aluminum is a light-weight, malleable, and corrosion-resistant metal that is used in many manufactured products, including aircraft, automobiles, bicycles, and kitchen utensils. As of recent reporting, the United States was the

⁴⁷ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

1 eighth largest producer of primary aluminum, with approximately 3 percent of the world total production (USGS
 2 2016). The United States was also a major importer of primary aluminum. The production of primary aluminum—in
 3 addition to consuming large quantities of electricity—results in process-related emissions of carbon dioxide (CO₂)
 4 and two perfluorocarbons (PFCs): perfluoromethane (CF₄) and perfluoroethane (C₂F₆).

5 Carbon dioxide is emitted during the aluminum smelting process when alumina (aluminum oxide, Al₂O₃) is reduced
 6 to aluminum using the Hall-Heroult reduction process. The reduction of the alumina occurs through electrolysis in a
 7 molten bath of natural or synthetic cryolite (Na₃AlF₆). The reduction cells contain a carbon (C) lining that serves as
 8 the cathode. Carbon is also contained in the anode, which can be a C mass of paste, coke briquettes, or prebaked C
 9 blocks from petroleum coke. During reduction, most of this C is oxidized and released to the atmosphere as CO₂.

10 Process emissions of CO₂ from aluminum production were estimated to be 2.8 MMT CO₂ Eq. (2,767 kt) in 2015
 11 (see Table 4-76). The C anodes consumed during aluminum production consist of petroleum coke and, to a minor
 12 extent, coal tar pitch. The petroleum coke portion of the total CO₂ process emissions from aluminum production is
 13 considered to be a non-energy use of petroleum coke, and is accounted for here and not under the CO₂ from Fossil
 14 Fuel Combustion source category of the Energy sector. Similarly, the coal tar pitch portion of these CO₂ process
 15 emissions is accounted for here.

16 **Table 4-76: CO₂ Emissions from Aluminum Production (MMT CO₂ Eq. and kt)**

Year	MMT CO ₂ Eq.	kt
1990	6.8	6,831
2005	4.1	4,142
2011	3.3	3,292
2012	3.4	3,439
2013	3.3	3,255
2014	2.8	2,833
2015	2.8	2,767

17 In addition to CO₂ emissions, the aluminum production industry is also a source of PFC emissions. During the
 18 smelting process, when the alumina ore content of the electrolytic bath falls below critical levels required for
 19 electrolysis, rapid voltage increases occur, which are termed “anode effects.” These anode effects cause C from the
 20 anode and fluorine from the dissociated molten cryolite bath to combine, thereby producing fugitive emissions of
 21 CF₄ and C₂F₆. In general, the magnitude of emissions for a given smelter and level of production depends on the
 22 frequency and duration of these anode effects. As the frequency and duration of the anode effects increase,
 23 emissions increase.

24 Since 1990, emissions of CF₄ and C₂F₆ have declined by 92 percent and 86 percent, respectively, to 1.5 MMT CO₂
 25 Eq. of CF₄ (0.3 kt) and 0.5 MMT CO₂ Eq. of C₂F₆ (0.04 kt) in 2015, as shown in Table 4-77 and Table 4-78. This
 26 decline is due both to reductions in domestic aluminum production and to actions taken by aluminum smelting
 27 companies to reduce the frequency and duration of anode effects. These actions include technology and operational
 28 changes such as employee training, use of computer monitoring, and changes in alumina feeding techniques. Since
 29 1990, aluminum production has declined by 61 percent, while the combined CF₄ and C₂F₆ emission rate (per metric
 30 ton of aluminum produced) has been reduced by 76 percent. Emissions decreased by approximately 21 percent
 31 between 2014 and 2015 due to decreases in aluminum production and in the rate of CF₄ and C₂F₆ emissions per
 32 metric ton of aluminum produced.

33 **Table 4-77: PFC Emissions from Aluminum Production (MMT CO₂ Eq.)**

Year	CF ₄	C ₂ F ₆	Total
1990	17.9	3.5	21.5
2005	2.9	0.6	3.4
2011	2.7	0.8	3.5
2012	2.3	0.7	2.9
2013	2.3	0.7	3.0

2014	1.9	0.6	2.5
2015	1.5	0.5	2.0

Note: Totals may not sum due to independent rounding.

1

2 **Table 4-78: PFC Emissions from Aluminum Production (kt)**

Year	CF ₄	C ₂ F ₆
1990	2.4	0.3
2005	0.4	+
2011	0.4	0.1
2012	0.4	0.1
2013	0.3	0.1
2014	0.3	0.1
2015	0.3	+

+ Does not exceed 0.05 kt.

3 In 2015, U.S. primary aluminum production totaled approximately 1.6 million metric tons, a 7 percent decrease from
 4 2014 production levels (USAA 2016a). In 2015, three companies managed production at eight operational primary
 5 aluminum smelters. One smelter remained on standby throughout the year, and two non-operating smelters were
 6 permanently shut down during 2015 (USGS 2016a). During 2015, monthly U.S. primary aluminum production was
 7 lower for every month in 2015, when compared to the corresponding months in 2014 (USGS 2016b; USGS 2015).

8 For 2016, total production for the January to August period was approximately 0.6 million metric tons compared to
 9 1.1 million metric tons for the same period in 2015, a 48 percent decrease (USAA 2016b). Based on the decrease in
 10 production, process CO₂ and PFC emissions are likely to be lower in 2016 compared to 2015 if there are no
 11 significant changes in process controls at operational facilities.

12 Methodology

13 Process CO₂ and PFC (i.e., CF₄ and C₂F₆) emission estimates from primary aluminum production for 2010 through
 14 2015 are available from EPA’s Greenhouse Gas Reporting Program (GHGRP)—Subpart F (Aluminum Production)
 15 (EPA 2016). Under EPA’s GHGRP, facilities began reporting primary aluminum production process emissions (for
 16 2010) in 2011; as a result, GHGRP data (for 2010 through 2015) are available to be incorporated into the Inventory.
 17 EPA’s GHGRP mandates that all facilities that contain an aluminum production process must report: CF₄ and C₂F₆
 18 emissions from anode effects in all prebake and Søderberg electrolysis cells, CO₂ emissions from anode
 19 consumption during electrolysis in all prebake and Søderberg cells, and all CO₂ emissions from onsite anode baking.
 20 To estimate the process emissions, EPA’s GHGRP uses the process-specific equations (and certain technology-
 21 specific defaults) detailed in subpart F (aluminum production).⁴⁸ These equations are based on the Tier 2/Tier 3
 22 IPCC (2006) methods for primary aluminum production, and Tier 1 methods when estimating missing data
 23 elements. It should be noted that the same methods (i.e., *2006 IPCC Guidelines*) were used for estimating the
 24 emissions prior to the availability of the reported GHGRP data in the Inventory.

25 Process CO₂ Emissions from Anode Consumption and Anode Baking

26 Carbon dioxide emission estimates for the years prior to the introduction of EPA’s GHGRP in 2010 were estimated
 27 *2006 IPCC Guidelines* methods, but individual facility reported data were combined with process-specific emissions
 28 modeling. These estimates were based on information previously gathered from EPA’s Voluntary Aluminum
 29 Industrial Partnership (VAIP) program, U.S. Geological Survey (USGS) Mineral Commodity reviews, and The

⁴⁸ Code of Federal Regulations, Title 40: Protection of Environment, Part 98: Mandatory Greenhouse Gas Reporting, Subpart F—Aluminum Production. See <www.epa.gov/ghgreporting/documents/pdf/infosheets/aluminumproduction.pdf>.

1 Aluminum Association (USAA) statistics, among other sources. Since pre- and post-GHGRP estimates use the same
2 methodology, emission estimates are comparable across the time series.

3 Most of the CO₂ emissions released during aluminum production occur during the electrolysis reaction of the C
4 anode, as described by the following reaction:

6 For prebake smelter technologies, CO₂ is also emitted during the anode baking process. These emissions can
7 account for approximately 10 percent of total process CO₂ emissions from prebake smelters.

8 Depending on the availability of smelter-specific data, the CO₂ emitted from electrolysis at each smelter was
9 estimated from: (1) the smelter's annual anode consumption, (2) the smelter's annual aluminum production and rate
10 of anode consumption (per ton of aluminum produced) for previous and/or following years, or (3) the smelter's
11 annual aluminum production and IPCC default CO₂ emission factors. The first approach tracks the consumption and
12 carbon content of the anode, assuming that all C in the anode is converted to CO₂. Sulfur, ash, and other impurities
13 in the anode are subtracted from the anode consumption to arrive at a C consumption figure. This approach
14 corresponds to either the IPCC Tier 2 or Tier 3 method, depending on whether smelter-specific data on anode
15 impurities are used. The second approach interpolates smelter-specific anode consumption rates to estimate
16 emissions during years for which anode consumption data are not available. This approach avoids substantial errors
17 and discontinuities that could be introduced by reverting to Tier 1 methods for those years. The last approach
18 corresponds to the IPCC Tier 1 method (IPCC 2006), and is used in the absence of present or historic anode
19 consumption data.

20 The equations used to estimate CO₂ emissions in the Tier 2 and 3 methods vary depending on smelter type (IPCC
21 2006). For Prebake cells, the process formula accounts for various parameters, including net anode consumption,
22 and the sulfur, ash, and impurity content of the baked anode. For anode baking emissions, the formula accounts for
23 packing coke consumption, the sulfur and ash content of the packing coke, as well as the pitch content and weight of
24 baked anodes produced. For Söderberg cells, the process formula accounts for the weight of paste consumed per
25 metric ton of aluminum produced, and pitch properties, including sulfur, hydrogen, and ash content.

26 Through the VAIP, anode consumption (and some anode impurity) data have been reported for 1990, 2000, 2003,
27 2004, 2005, 2006, 2007, 2008, and 2009. Where available, smelter-specific process data reported under the VAIP
28 were used; however, if the data were incomplete or unavailable, information was supplemented using industry
29 average values recommended by IPCC (2006). Smelter-specific CO₂ process data were provided by 18 of the 23
30 operating smelters in 1990 and 2000, by 14 out of 16 operating smelters in 2003 and 2004, 14 out of 15 operating
31 smelters in 2005, 13 out of 14 operating smelters in 2006, 5 out of 14 operating smelters in 2007 and 2008, and 3 out
32 of 13 operating smelters in 2009. For years where CO₂ emissions data or CO₂ process data were not reported by
33 these companies, estimates were developed through linear interpolation, and/or assuming representative (e.g.,
34 previously reported or industry default) values.

35 In the absence of any previous historical smelter specific process data (i.e., 1 out of 13 smelters in 2009; 1 out of 14
36 smelters in 2006, 2007, and 2008; 1 out of 15 smelters in 2005; and 5 out of 23 smelters between 1990 and 2003),
37 CO₂ emission estimates were estimated using Tier 1 Söderberg and/or Prebake emission factors (metric ton of CO₂
38 per metric ton of aluminum produced) from IPCC (2006).

39 **Process PFC Emissions from Anode Effects**

40 Smelter-specific PFC emissions from aluminum production for 2010 through 2015 were reported to EPA under its
41 GHGRP. To estimate their PFC emissions and report them under EPA's GHGRP, smelters use an approach identical
42 to the Tier 3 approach in the *2006 IPCC Guidelines* (IPCC 2006). Specifically, they use a smelter-specific slope
43 coefficient as well as smelter-specific operating data to estimate an emission factor using the following equation

$$44 \quad PFC = S \times AE$$
$$45 \quad AE = F \times D$$

46 where,

$$47 \quad PFC = CF_4 \text{ or } C_2F_6, \text{ kg/MT aluminum}$$

48

- 1 S = Slope coefficient, PFC/AE
- 2 AE = Anode effect, minutes/cell-day
- 3 F = Anode effect frequency per cell-day
- 4 D = Anode effect duration, minutes

6 They then multiply this emission factor by aluminum production to estimate PFC emissions. All U.S. aluminum
7 smelters are required to report their emissions under EPA’s GHGRP.

8 Perfluorocarbon emissions for the years prior to 2010 were estimated using the same equation, but the slope-factor
9 used for some smelters was technology-specific rather than smelter-specific, making the method a Tier 2 rather than
10 a Tier 3 approach for those smelters. Emissions and background data were reported to EPA under the VAIP. For
11 1990 through 2009, smelter-specific slope coefficients were available and were used for smelters representing
12 between 30 and 94 percent of U.S. primary aluminum production. The percentage changed from year to year as
13 some smelters closed or changed hands and as the production at remaining smelters fluctuated. For smelters that did
14 not report smelter-specific slope coefficients, IPCC technology-specific slope coefficients were applied (IPCC
15 2006). The slope coefficients were combined with smelter-specific anode effect data collected by aluminum
16 companies and reported under the VAIP to estimate emission factors over time. For 1990 through 2009, smelter-
17 specific anode effect data were available for smelters representing between 80 and 100 percent of U.S. primary
18 aluminum production. Where smelter-specific anode effect data were not available, representative values (e.g.,
19 previously reported or industry averages) were used.

20 For all smelters, emission factors were multiplied by annual production to estimate annual emissions at the smelter
21 level. For 1990 through 2009, smelter-specific production data were available for smelters representing between 30
22 and 100 percent of U.S. primary aluminum production. (For the years after 2000, this percentage was near the high
23 end of the range.) Production at non-reporting smelters was estimated by calculating the difference between the
24 production reported under VAIP and the total U.S. production supplied by USGS or USAA, and then allocating this
25 difference to non-reporting smelters in proportion to their production capacity. Emissions were then aggregated
26 across smelters to estimate national emissions.

27 Between 1990 and 2009, production data were provided under the VAIP by 21 of the 23 U.S. smelters that operated
28 during at least part of that period. For the non-reporting smelters, production was estimated based on the difference
29 between reporting smelters and national aluminum production levels (USGS and USAA 1990 through 2009), with
30 allocation to specific smelters based on reported production capacities (USGS 1990 through 2009).

31 National primary aluminum production data for 2015 were obtained via USAA (USAA 2016a). For 1990 through
32 2001, and 2006 (see Table 4-79) data were obtained from USGS *Mineral Industry Surveys: Aluminum Annual
33 Report* (USGS 1995, 1998, 2000, 2001, 2002, 2007). For 2002 through 2005, and 2007 through 2014, national
34 aluminum production data were obtained from the USAA’s Primary Aluminum Statistics (USAA 2004 through
35 2006, 2008 through 2015).

36 **Table 4-79: Production of Primary Aluminum (kt)**

Year	kt
1990	4,048
2005	2,478
2011	1,986
2012	2,070
2013	1,948
2014	1,710
2015	1,587

37 Uncertainty and Time-Series Consistency

38 Uncertainty was assigned to the CO₂, CF₄, and C₂F₆ emission values reported by each individual facility to EPA’s
39 GHGRP. As previously mentioned, the methods for estimating emissions for EPA’s GHGRP and this report are the

same, and follow the 2006 IPCC Guidelines methodology. As a result, it was possible to assign uncertainty bounds (and distributions) based on an analysis of the uncertainty associated with the facility-specific emissions estimated for previous Inventory years. Uncertainty surrounding the reported CO₂, CF₄, and C₂F₆ emission values were determined to have a normal distribution with uncertainty ranges of ±6, ±16, and ±20 percent, respectively. A Monte Carlo analysis was applied to estimate the overall uncertainty of the CO₂, CF₄, and C₂F₆ emission estimates for the U.S. aluminum industry as a whole, and the results are provided below.

The results of this Approach 2 quantitative uncertainty analysis are summarized in Table 4-80. Aluminum production-related CO₂ emissions were estimated to be between 2.7 and 2.8 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 2 percent below to 2 percent above the emission estimate of 2.8 MMT CO₂ Eq. Also, production-related CF₄ emissions were estimated to be between 1.4 and 1.6 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 7 percent below to 7 percent above the emission estimate of 1.5 MMT CO₂ Eq. Finally, aluminum production-related C₂F₆ emissions were estimated to be between 0.4 and 0.6 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 13 percent below to 13 percent above the emission estimate of 0.5 MMT CO₂ Eq.

Table 4-80: Approach 2 Quantitative Uncertainty Estimates for CO₂ and PFC Emissions from Aluminum Production (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Aluminum Production	CO ₂	2.8	2.7	2.8	-2%	+2%
Aluminum Production	CF ₄	1.5	1.4	1.6	-7%	+7%
Aluminum Production	C ₂ F ₆	0.5	0.4	0.6	-13%	+13%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

QA/QC and Verification

Tier 1 and Tier 2 QA/QC activities were conducted consistent with the U.S. QA/QC plan. Source-specific quality control measures for the Aluminum Production category included checking input data, documentation, and calculations to ensure data were properly handled through the inventory process. Errors that were found during this process were corrected as necessary.

4.19 Magnesium Production and Processing (IPCC Source Category 2C4)

The magnesium metal production and casting industry uses sulfur hexafluoride (SF₆) as a cover gas to prevent the rapid oxidation of molten magnesium in the presence of air. Sulfur hexafluoride has been used in this application around the world for more than thirty years. A dilute gaseous mixture of SF₆ with dry air and/or carbon dioxide (CO₂) is blown over molten magnesium metal to induce and stabilize the formation of a protective crust. A small portion of the SF₆ reacts with the magnesium to form a thin molecular film of mostly magnesium oxide and magnesium fluoride. The amount of SF₆ reacting in magnesium production and processing is considered to be negligible and thus all SF₆ used is assumed to be emitted into the atmosphere. Alternative cover gases, such as AM-cover™ (containing HFC-134a), Novec™ 612 (FK-5-1-12) and dilute sulfur dioxide (SO₂) systems can, and are being used by some facilities in the United States. However, many facilities in the United States are still using traditional SF₆ cover gas systems.

1 The magnesium industry emitted 0.9 MMT CO₂ Eq. (0.04 kt) of SF₆, 0.09 MMT CO₂ Eq. (0.06 kt) of HFC-134a,
 2 and 0.003 MMT CO₂ Eq. (2.6 kt) of CO₂ in 2015. This represents a decrease of approximately 5 percent from total
 3 2014 emissions (see Table 4-81). The decrease can be attributed to reduction in primary and die casting SF₆
 4 emissions between 2014 and 2015 as reported through EPA’s Greenhouse Gas Reporting Program (GHGRP). In
 5 2015, SF₆ emissions decreased by 7 percent. The reduction in SF₆ emissions is likely due in part to decreased
 6 production from reporting facilities in 2015. The decrease in SF₆ emissions can also be attributed to continuing
 7 industry efforts to utilize SF₆ alternatives, such as HFC-134a, Novec™612 and SO₂, to reduce greenhouse gas
 8 emissions. In 2015, total HFC-134a emissions increased from 0.08 MMT CO₂ Eq. to 0.09 MMT CO₂ Eq., or a 19
 9 percent increase as compared to 2014 emissions. This is mainly attributable to the increased use of this alternative
 10 for primary production. FK 5-1-12 emissions increased by 8 percent from 0.0050 kt to 0.0054 kt. The emissions of
 11 the carrier gas, CO₂, increased from 2.3 kt in 2014 to 2.6 kt in 2015.

16 Methodology

17 Emission estimates for the magnesium industry incorporate information provided by industry participants in EPA’s
 18 SF₆ Emission Reduction Partnership for the Magnesium Industry as well as emissions data reported through Subpart
 19 T (Magnesium Production and Processing) of the EPA’s GHGRP. The Partnership started in 1999 and, in 2010,
 20 participating companies represented 100 percent of U.S. primary and secondary production and 16 percent of the
 21 casting sector production (i.e., die, sand, permanent mold, wrought, and anode casting). SF₆ Emissions for 1999
 22 through 2010 from primary production, secondary production (i.e., recycling), and die casting were generally
 23 reported by Partnership participants. Partners reported their SF₆ consumption, which is assumed to be equivalent to
 24 emissions. Along with SF₆, some Partners also reported their HFC-134a and FK 5-1-12 usage, which is also
 25 assumed to be equal to emissions. 2010 was the last reporting year under the Partnership. Emissions data for 2011
 26 through 2015 are obtained through EPA’s GHGRP. Under the program, owners or operators of facilities that have a
 27 magnesium production or casting process must report emissions from use of cover or carrier gases, which include
 28 SF₆, HFC-134a, FK 5-1-12 and CO₂. Consequently, cover and carrier gas emissions from magnesium production
 29 and processing were estimated for three time periods, depending on the source of the emissions data: 1990 through
 30 1998, 1999 through 2010, and 2011 through 2015. The methodologies described below also make use of magnesium
 31 production data published by the U.S. Geological Survey (USGS).

1990 through 1998

To estimate emissions for 1990 through 1998, industry SF₆ emission factors were multiplied by the corresponding metal production and consumption (casting) statistics from USGS. For this period, it was assumed that there was no use of HFC-134a or FK 5-1-12 cover gases and hence emissions were not estimated for these alternatives.

Sulfur hexafluoride emission factors from 1990 through 1998 were based on a number of sources and assumptions. Emission factors for primary production were available from U.S. primary producers for 1994 and 1995. The primary production emission factors were 1.2 kg SF₆ per metric ton for 1990 through 1993, and 1.1 kg SF₆ per metric ton for 1994 through 1997. The emission factor for secondary production from 1990 through 1998 was assumed to be constant at the 1999 average Partner value. An emission factor for die casting of 4.1 kg SF₆ per metric ton, which was available for the mid-1990s from an international survey (Gjestland and Magers 1996), was used for years 1990 through 1996. For 1996 through 1998, the emission factor for die casting was assumed to decline linearly to the level estimated based on Partner reports in 1999. This assumption is consistent with the trend in SF₆ sales to the magnesium sector that is reported in the RAND survey of major SF₆ manufacturers, which shows a decline of 70 percent from 1996 to 1999 (RAND 2002). Sand casting emission factors for 1990 through 2001 were assumed to be the same as the 2002 emission factor. The emission factors for the other processes (i.e., permanent mold, wrought, and anode casting), about which less is known, were assumed to remain constant at levels defined in Table 4-81. These emission factors for the other processes (i.e., permanent mold, wrought, and anode casting) were based on discussions with industry representatives.

The quantities of CO₂ carrier gas used for each production type have been estimated using the 1999 estimated CO₂ emissions data and the annual calculated rate of change of SF₆ use in the 1990 through 1999 time period. For each year and production type, the rate of change of SF₆ use between the current year and the subsequent year was first estimated. This rate of change is then applied to the CO₂ emissions of the subsequent year to determine the CO₂ emission of the current year. The emissions of carrier gases for permanent mold, wrought and anode processes are not estimated in this Inventory.

1999 through 2010

The 1999 through 2010 emissions from primary and secondary production are based on information provided by EPA's industry Partners. In some instances, there were years of missing Partner data, including SF₆ consumption and metal processed. For these situations, emissions were estimated through interpolation where possible, or by holding company-reported emissions (as well as production) constant from the previous year. For alternative cover gases, including HFC-134a and FK 5-1-12, mainly reported data was relied upon. That is, unless a Partner reported using an alternative cover gas, it was not assumed it was used. Emissions of alternate gases were also estimated through linear interpolation where possible.

The die casting emission estimates for 1999 through 2010 are also based on information supplied by industry Partners. When a Partner was determined to be no longer in production, its metal production and usage rates were set to zero. Missing data on emissions or metal input was either interpolated or held constant at the last available reported value. In 1999 and from 2008 through 2010, Partners did not account for all die casting tracked by USGS, and, therefore, it was necessary to estimate the emissions of die casters who were not Partners. For 1999, die casters who were not Partners were assumed to be similar to Partners who cast small parts. Due to process requirements, these casters consume larger quantities of SF₆ per metric ton of processed magnesium than casters that process large parts. Consequently, emission estimates from this group of die casters were developed using an average emission factor of 5.2 kg SF₆ per metric ton of magnesium. This emission factor was developed using magnesium production and SF₆ usage data for the year 1999. For 2008 through 2010, the characteristics of the die casters who were not Partners were not well known, and therefore the emission factor for these die casters was set equal to 3.0 kg SF₆ per metric ton of magnesium, the average of the emission factors reported over the same period by the die casters who were Partners.

The emissions from other casting operations were estimated by multiplying emission factors (kg SF₆ per metric ton of metal produced or processed) by the amount of metal produced or consumed from USGS, with the exception of some years for which Partner sand casting emissions data are available. The emission factors for sand casting activities were acquired through the data reported by the Partnership for 2002 to 2006. For 1999 through 2001, the sand casting emission factor was held constant at the 2002 Partner-reported level. For 2007 through 2010, the sand

1 casting Partner did not report and the reported emission factor from 2005 was applied to the Partner and to all other
2 sand casters. Activity data for 2005 was obtained from USGS (USGS 2005b).

3 The emission factors for primary production, secondary production and sand casting for the 1999 to 2010 are not
4 published to protect company-specific production information. However, the emission factor for primary production
5 has not risen above the average 1995 Partner value of 1.1 kg SF₆ per metric ton. The emission factors for the other
6 industry sectors (i.e., permanent mold, wrought, and anode casting) were based on discussions with industry
7 representatives. The emission factors for casting activities are provided below in Table 4-83.

8 The emissions of HFC-134a and FK-5-1-12 were included in the estimates for only instances where Partners
9 reported that information to the Partnership. Emissions of these alternative cover gases were not estimated for
10 instances where emissions were not reported.

11 Carbon dioxide carrier gas emissions were estimated using the emission factors developed based on EPA's GHGRP-
12 reported carrier gas and cover gas data, by production type. It was assumed that the use of carrier gas, by production
13 type, is proportional to the use of cover gases. Therefore, an emission factor, in kg CO₂ per kg cover gas and
14 weighted by the cover gases used, was developed for each of the production types. EPA's GHGRP data on which
15 these emissions factors are based was available for primary, secondary, die casting and sand casting. The emission
16 factors were applied to the total quantity of all cover gases used (SF₆, HFC-134a, and FK-5-1-12) by production
17 type in this time period. Carrier gas emissions for the 1999 through 2010 time period were only estimated for those
18 Partner companies that reported using CO₂ as a carrier gas through the GHGRP. Using this approach helped ensure
19 time series consistency. The emissions of carrier gases for permanent mold, wrought and anode processes are not
20 estimated in this Inventory.

21 **Table 4-83: SF₆ Emission Factors (kg SF₆ per Metric Ton of Magnesium)**

Year	Die Casting ^a	Permanent Mold	Wrought	Anodes
1999	2.14 ^b	2	1	1
2000	0.72	2	1	1
2001	0.72	2	1	1
2002	0.71	2	1	1
2003	0.81	2	1	1
2004	0.79	2	1	1
2005	0.77	2	1	1
2006	0.88	2	1	1
2007	0.64	2	1	1
2008	0.10	2	1	1
2009	2.30	2	1	1
2010	2.94	2	1	1

^a Weighted average includes all die casters, Partners and non-Partners. For the majority of the time series (2000 to 2007), Partners made up 100 percent of die casters in the United States.

^b Weighted average that includes an estimated emission factor of 5.2 kg SF₆ per metric ton of magnesium for die casters that do not participate in the Partnership.

22 **2011 through 2015**

23 For 2011 through 2015, for the primary and secondary producers, EPA's GHGRP-reported cover and carrier gases
24 emissions data were used. For die and sand casting, some emissions data was obtained through EPA's GHGRP. The
25 balance of the emissions for these industry segments were estimated based on previous Partner reporting (i.e., for
26 Partners that did not report emissions through EPA's GHGRP) or were estimated by multiplying emission factors by
27 the amount of metal produced or consumed. Partners who did not report through EPA's GHGRP were assumed to
28 have continued to emit SF₆ at the last reported level, which was from 2010 in most cases. All Partners were assumed
29 to have continued to consume magnesium at the last reported level. Where the total metal consumption estimated for
30 the Partners fell below the U.S. total reported by USGS, the difference was multiplied by the emission factors
31 discussed in the section above. For the other types of production and processing (i.e., permanent mold, wrought, and
32 anode casting), emissions were estimated by multiplying the industry emission factors with the metal production or
33 consumption statistics obtained from USGS (USGS 2015).

1 Uncertainty and Time-Series Consistency

2 Uncertainty surrounding the total estimated emissions in 2015 is attributed to the uncertainties around SF₆, HFC-
 3 134a, and CO₂ emission estimates. To estimate the uncertainty surrounding the estimated 2015 SF₆ emissions from
 4 magnesium production and processing, the uncertainties associated with three variables were estimated: (1)
 5 emissions reported by magnesium producers and processors for 2015 through EPA’s GHGRP, (2) emissions
 6 estimated for magnesium producers and processors that reported via the Partnership in prior years but did not report
 7 2015 emissions through EPA’s GHGRP, and (3) emissions estimated for magnesium producers and processors that
 8 did not participate in the Partnership or report through EPA’s GHGRP. An uncertainty of 5 percent was assigned to
 9 the emissions (usage) data reported by each GHGRP reporter for all the cover and carrier gases (per the *2006 IPCC*
 10 *Guidelines*). If facilities did not report emissions data during the current reporting year through EPA’s GHGRP
 11 reporting program, SF₆ emissions data were held constant at the most recent available value reported through the
 12 Partnership. The uncertainty associated with these values was estimated to be 30 percent for each year of
 13 extrapolation. Alternate cover gas and carrier gases data was set equal to zero if the facilities did not report via the
 14 GHGRP program. One known sand caster (the lone Partner) has not reported since 2007 and its activity and
 15 emission factor were held constant at 2005 levels due to a reporting anomaly in 2006 because of malfunctions at the
 16 facility. The uncertainty associated with the SF₆ usage for the sand casting Partner was 90 percent. As with the non-
 17 reporting facility, the uncertainty with this value was estimated to be 30 percent for each year of extrapolation,
 18 increasing the uncertainty this year. For those industry processes that are not represented in the Partnership, such as
 19 permanent mold and wrought casting, SF₆ emissions were estimated using production and consumption statistics
 20 reported by USGS and estimated process-specific emission factors (see Table 4-84). The uncertainties associated
 21 with the emission factors and USGS-reported statistics were assumed to be 75 percent and 25 percent, respectively.
 22 Emissions associated with die casting and sand casting activities utilized emission factors based on Partner reported
 23 data with an uncertainties of 75 percent. In general, where precise quantitative information was not available on the
 24 uncertainty of a parameter, a conservative (upper-bound) value was used.

25 Additional uncertainties exist in these estimates that are not addressed in this methodology, such as the basic
 26 assumption that SF₆ neither reacts nor decomposes during use. The melt surface reactions and high temperatures
 27 associated with molten magnesium could potentially cause some gas degradation. Previous measurement studies
 28 have identified SF₆ cover gas degradation in die casting applications on the order of 20 percent (Bartos et al. 2007).
 29 Sulfur hexafluoride may also be used as a cover gas for the casting of molten aluminum with high magnesium
 30 content; however, the extent to which this technique is used in the United States is unknown.

31 The results of this Approach 2 quantitative uncertainty analysis are summarized in Table 4-84. Total emissions
 32 associated with magnesium production and processing were estimated to be between 1.0 and 1.1 MMT CO₂ Eq. at
 33 the 95 percent confidence level. This indicates a range of approximately 6 percent below to 6 percent above the
 34 2015 emission estimate of 1.0 MMT CO₂ Eq. The uncertainty estimates for 2015 are smaller relative to the
 35 uncertainty reported for 2014 in the previous Inventory report. In the previous Inventory, the emissions factor of die-
 36 casting had a significant impact on the uncertainty because of relatively high emissions from the facilities that do not
 37 report under the EPA’s GHGRP. This year, there was a decrease in production from non-GHGRP reporting die
 38 casting facilities, lowering the uncertainty bounds on the total emission estimate.

39 **Table 4-84: Approach 2 Quantitative Uncertainty Estimates for SF₆, HFC-134a and CO₂**
 40 **Emissions from Magnesium Production and Processing (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Magnesium Production	SF ₆ , HFC-134a and CO ₂	1.0	1.0	1.1	-6%	+6%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

41 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 42 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 43 above.

1 Recalculations Discussion

2 For one GHGRP-reporting facility, a recalculation for 2014 CO₂ emissions was performed to ensure methodological
3 consistency and based on the availability of new data. The CO₂ emissions for this facility in 2014 were previously
4 held constant at 2013 levels based on data reported through the EPA's GHGRP. Since the facility reported 2015
5 data, but did report in 2014, the estimate of 2014 emissions has been revised by interpolating the reported emissions
6 between 2013 and 2015, reported via EPA's GHGRP. This has caused a slight decrease in the CO₂ emissions for
7 2014 compared to the previous Inventory.

8 One facility revised its GHGRP reported data for 2014 HFC-134a emissions, resulting in a decrease in overall 2014
9 emissions.

10 A facility that had not previously reported under the GHGRP reported 2014 and 2015 SF₆ die-casting emissions in
11 2016. Since production levels were held constant from 2014 data, the resulting adjustment to non-GHGRP casting
12 production led to a slight decrease in 2014 SF₆ emissions.

13 Planned Improvements

14 Cover gas research conducted over the last decade has found that SF₆ used for magnesium melt protection can have
15 degradation rates on the order of 20 percent in die casting applications (Bartos et al. 2007). Current emission
16 estimates assume (per the *2006 IPCC Guidelines*) that all SF₆ utilized is emitted to the atmosphere. Additional
17 research may lead to a revision of the *2006 IPCC Guidelines* to reflect this phenomenon and until such time,
18 developments in this sector will be monitored for possible application to the inventory methodology.

19 Usage and emission details of carrier gases in permanent mold, wrought and anode processes will be researched as
20 part of a future inventory. Based on this research, it will be determined if CO₂ carrier gas emissions are to be
21 estimated.

22 4.20 Lead Production (IPCC Source Category 23 2C5)

24 Lead production in the United States consists of both primary and secondary processes—both of which emit carbon
25 dioxide (CO₂) (Sjardin 2003). Emissions from fuels consumed for energy purposes during the production of lead are
26 accounted for in the Energy chapter.

27 Primary production of lead through the direct smelting of lead concentrate produces CO₂ emissions as the lead
28 concentrates are reduced in a furnace using metallurgical coke (Sjardin 2003). Primary lead production, in the form
29 of direct smelting, previously occurred at a single smelter in Missouri. This primary lead smelter was closed at the
30 end of 2013. In 2014, the smelter processed a small amount of residual lead during demolition of the site (USGS
31 2015). In 2015, the smelter processed no lead (USGS 2016).

32 Similar to primary lead production, CO₂ emissions from secondary lead production result when a reducing agent,
33 usually metallurgical coke, is added to the smelter to aid in the reduction process. Carbon dioxide emissions from
34 secondary production also occur through the treatment of secondary raw materials (Sjardin 2003). Secondary
35 production primarily involves the recycling of lead acid batteries and post-consumer scrap at secondary smelters. Of
36 all the domestic secondary smelters operational in 2015, 11 smelters had capacities of 30,000 tons or more and were
37 collectively responsible for more than 95 percent of secondary lead production in 2015 (USGS 2016). Secondary
38 lead production has increased in the United States over the past decade while primary lead production has decreased
39 to production levels of zero. In 2015, secondary lead production accounted for 100 percent of total lead production.
40 As was the case in 2014, the lead-acid battery industry accounted for about 90 percent of the reported U.S. lead
41 consumption in 2015 (USGS 2016).

42 In 2015, total secondary lead production in the United States was slightly lower than that in 2014. Increased
43 production at a couple of smelters was expected to be offset by temporary closure of one smelter. In 2014, a

producer temporarily shut down operations of a lead smelter in Vernon, CA (90,000 metric ton capacity smelter) due to environmental concerns from state regulators. As stated in the previous inventory report, the company intended to restart operations in 2015, after making improvements to the plant, but closed the plant instead. In 2015, one secondary producer announced plans to build a new plant in Nevada capable of producing high-purity lead for use in advanced lead-acid batteries; this plant is expected to be built in 2016. Increases in exports of spent lead-acid batteries in recent years have decreased the amount of scrap available to secondary smelters (USGS 2016).

U.S. primary lead production reached production levels of zero, a decrease of 100 percent from 2014 to 2015, and has also decreased by 100 percent since 1990. This is due to the closure of the only domestic primary lead smelter in 2013 (year-end). In 2015, U.S. secondary lead production dropped slightly from 2014 levels (decrease of 1 percent), and has increased by 21 percent since 1990 (USGS 1995 through 2013, 2014, 2015, 2016).

In 2015, U.S. primary and secondary lead production totaled 1,120,000 metric tons (USGS 2016). The resulting emissions of CO₂ from 2015 lead production were estimated to be 0.5 MMT CO₂ Eq. (504 kt) (see Table 4-85). All of the 2015 lead production is from secondary processes, which accounted for 100 percent of total 2015 CO₂ emissions from lead production. At last reporting, the United States was the third largest mine producer of lead in the world, behind China and Australia, accounting for approximately 8 percent of world production in 2015 (USGS 2016).

Table 4-85: CO₂ Emissions from Lead Production (MMT CO₂ Eq. and kt)

Year	MMT CO ₂ Eq.	kt
1990	0.5	516
2005	0.6	553
2011	0.5	538
2012	0.5	527
2013	0.5	546
2014	0.5	509
2015	0.5	504

After a steady increase in total emissions from 1995 to 2000, total emissions have gradually decreased since 2000 and are currently lower than 1990 levels.

Methodology

The methods used to estimate emissions for lead production⁴⁹ are based on Sjardin's work (Sjardin 2003) for lead production emissions and Tier 1 methods from the 2006 IPCC Guidelines. The Tier 1 equation is as follows:

$$CO_2 \text{ Emissions} = (DS \times EF_{DS}) + (S \times EF_S)$$

where,

DS	=	Lead produced by direct smelting, metric ton
S	=	Lead produced from secondary materials
EF _{DS}	=	Emission factor for direct Smelting, metric tons CO ₂ /metric ton lead product
EF _S	=	Emission factor for secondary materials, metric tons CO ₂ /metric ton lead product

For primary lead production using direct smelting, Sjardin (2003) and the IPCC (2006) provide an emission factor of 0.25 metric tons CO₂/metric ton lead. For secondary lead production, Sjardin (2003) and IPCC (2006) provide an emission factor of 0.25 metric tons CO₂/metric ton lead for direct smelting, as well as an emission factor of 0.2 metric tons CO₂/metric ton lead produced for the treatment of secondary raw materials (i.e., pretreatment of lead

⁴⁹ EPA has not integrated aggregated facility-level Greenhouse Gas Reporting Program (GHGRP) information to inform these estimates. The aggregated information (e.g., activity data and emissions) associated with Lead Production did not meet criteria to shield underlying confidential business information (CBI) from public disclosure.

1 acid batteries). Since the secondary production of lead involves both the use of the direct smelting process and the
 2 treatment of secondary raw materials, Sjardin recommends an additive emission factor to be used in conjunction
 3 with the secondary lead production quantity. The direct smelting factor (0.25) and the sum of the direct smelting and
 4 pretreatment emission factors (0.45) are multiplied by total U.S. primary and secondary lead production,
 5 respectively, to estimate CO₂ emissions.

6 The 1990 through 2015 activity data for primary and secondary lead production (see Table 4-86) were obtained from
 7 the U.S. Geological Survey (USGS 1995 through 2013, 2014, 2015, 2016).

8 **Table 4-86: Lead Production (Metric Tons)**

Year	Primary	Secondary
1990	404,000	922,000
2005	143,000	1,150,000
2011	118,000	1,130,000
2012	111,000	1,110,000
2013	114,000	1,150,000
2014	1,000	1,130,000
2015	0	1,120,000

9 **Uncertainty and Time-Series Consistency – TO BE UPDATED** 10 **FOR FINAL INVENTORY REPORT**

11 Uncertainty associated with lead production relates to the emission factors and activity data used. The direct
 12 smelting emission factor used in primary production is taken from Sjardin (2003) who averaged the values provided
 13 by three other studies (Dutrizac et al. 2000; Morris et al. 1983; Ullman 1997). For secondary production, Sjardin
 14 (2003) added a CO₂ emission factor associated with battery treatment. The applicability of these emission factors to
 15 plants in the United States is uncertain. There is also a smaller level of uncertainty associated with the accuracy of
 16 primary and secondary production data provided by the USGS. This information is collected by USGS via voluntary
 17 surveys.

18 The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-87. Lead production CO₂
 19 emissions in 2015 were estimated to be between 0.4 and 0.6 MMT CO₂ Eq. at the 95 percent confidence level. This
 20 indicates a range of approximately 15 percent below and 16 percent above the emission estimate of 0.5 MMT CO₂
 21 Eq.

22 **Table 4-87: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Lead**
 23 **Production (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Lead Production	CO ₂	0.5	0.4	0.6	-15%	+16%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

24 Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990
 25 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 26 above.

1 Recalculations Discussion

2 For the current Inventory, primary and secondary lead production quantities were revised to reflect the most recent
3 USGS publication (USGS 2016). This change resulted in a 2 percent increase in the 2014 emission estimate
4 compared to the previous Inventory report.

5 Planned Improvements

6 Pending resources and prioritization of improvements for more significant sources, EPA will continue to evaluate
7 and analyze data reported under EPA's GHGRP that would be useful to improve the emission estimates and
8 category specific QC for the Lead Production source category, in particular considering completeness of reported
9 lead production given the reporting threshold. Given the small number of facilities in the US, particular attention
10 will be made to risks for disclosing CBI and ensuring time series consistency of the emissions estimates presented in
11 future Inventory reports, consistent with IPCC and UNFCCC guidelines. This is required as the facility-level
12 reporting data from EPA's GHGRP, with the program's initial requirements for reporting of emissions in calendar
13 year 2010, are not available for all inventory years (i.e., 1990 through 2009) as required for this Inventory. In
14 implementing improvements and integration of data from EPA's GHGRP, the latest guidance from the IPCC on the
15 use of facility-level data in national inventories will be relied upon.⁵⁰ EPA is still assessing the possibility of
16 including this planned improvement in future Inventory reports.

17 4.21 Zinc Production (IPCC Source Category 18 2C6)

19 Zinc production in the United States consists of both primary and secondary processes. Of the primary and
20 secondary processes used in the United States, only the electrothermic and Waelz kiln secondary processes result in
21 non-energy carbon dioxide (CO₂) emissions (Viklund-White 2000). Emissions from fuels consumed for energy
22 purposes during the production of zinc are accounted for in the Energy chapter.

23 The majority of zinc produced in the United States is used for galvanizing. Galvanizing is a process where zinc
24 coating is applied to steel in order to prevent corrosion. Zinc is used extensively for galvanizing operations in the
25 automotive and construction industry. Zinc is also used in the production of zinc alloys and brass and bronze alloys
26 (e.g., brass mills, copper foundries, and copper ingot manufacturing). Zinc compounds and dust are also used, to a
27 lesser extent, by the agriculture, chemicals, paint, and rubber industries.

28 Primary production in the United States is conducted through the electrolytic process, while secondary techniques
29 include the electrothermic and Waelz kiln processes, as well as a range of other metallurgical, hydrometallurgical,
30 and pyrometallurgical processes. Worldwide primary zinc production also employs a pyrometallurgical process
31 using the Imperial Smelting Furnace process; however, this process is not used in the United States (Sjardin 2003).

32 In the electrothermic process, roasted zinc concentrate and secondary zinc products enter a sinter feed where they
33 are burned to remove impurities before entering an electric retort furnace. Metallurgical coke is added to the electric
34 retort furnace as a carbon-containing reductant. This concentration step, using metallurgical coke and high
35 temperatures, reduces the zinc oxides and produces vaporized zinc, which is then captured in a vacuum condenser.
36 This reduction process also generates non-energy CO₂ emissions.

39 In the Waelz kiln process, electric arc furnace (EAF) dust, which is captured during the recycling of galvanized
40 steel, enters a kiln along with a reducing agent (typically carbon-containing metallurgical coke). When kiln

⁵⁰ See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

1 temperatures reach approximately 1,100 to 1,200 degrees Celsius, zinc fumes are produced, which are combusted
 2 with air entering the kiln. This combustion forms zinc oxide, which is collected in a baghouse or electrostatic
 3 precipitator, and is then leached to remove chloride and fluoride. The use of carbon-containing metallurgical coke in
 4 a high-temperature fuming process results in non-energy CO₂ emissions. Through this process, approximately 0.33
 5 metric tons of zinc is produced for every metric ton of EAF dust treated (Viklund-White 2000).

6 The only companies in the United States that use emissive technology to produce secondary zinc products are
 7 Horsehead, PIZO, and Steel Dust Recycling. For Horsehead, EAF dust is recycled in Waelz kilns at their Beaumont,
 8 TX; Calumet, IL; Palmerton, PA; Rockwood, TN; and Barnwell, SC facilities. These Waelz kiln facilities produce
 9 intermediate zinc products (crude zinc oxide or calcine), most of which was transported to their Monaca, PA facility
 10 where the products were smelted into refined zinc using electrothermic technology. In April 2014, Horsehead
 11 permanently shut down their Monaca smelter. This was replaced by their new facility in Mooresboro, NC. The new
 12 Mooresboro facility uses a hydrometallurgical process (i.e., solvent extraction with electrowinning technology) to
 13 produce zinc products. The current capacity of the new facility is 155,000 short tons, with plans to expand to
 14 170,000 short tons per year. During the fourth quarter of 2015, the Mooresboro facility was only operating at
 15 approximately 25 percent of capacity (Horsehead 2016). Direct consumption of coal, coke, and natural gas have
 16 been replaced with electricity consumption at the new Mooresboro facility. The new facility is reported to have a
 17 significantly lower greenhouse gas and other air emissions than the Monaca smelter (Horsehead 2012b).

18 The Mooresboro facility uses leaching and solvent extraction (SX) technology combined with electrowinning,
 19 melting, and casting technology. In this process, Waelz Oxide (WOX) is first washed in water to remove soluble
 20 elements such as chlorine, potassium, and sodium, and then is leached in a sulfuric acid solution to dissolve the
 21 contained zinc creating a pregnant liquor solution (PLS). The PLS is then processed in a solvent extraction step in
 22 which zinc is selectively extracted from the PLS using an organic solvent creating a purified zinc-loaded electrolyte
 23 solution. The loaded electrolyte solution is then fed into the electrowinning process in which electrical energy is
 24 applied across a series of anodes and cathodes submerged in the electrolyte solution causing the zinc to deposit on
 25 the surfaces of the cathodes. As the zinc metal builds up on these surfaces, the cathodes are periodically harvested in
 26 order to strip the zinc from their surfaces (Horsehead 2015). Hydrometallurgical production processes are assumed
 27 to be non-emissive since no carbon is used in these processes (Sjardin 2003).

28 PIZO and Steel Dust Recycling recycle EAF dust into intermediate zinc products using Waelz kilns, and then sell
 29 the intermediate products to companies who smelt it into refined products.

30 In 2015, U.S. primary and secondary refined zinc production were estimated to total 175,000 metric tons (USGS
 31 2016 (see Table 4-88). Domestic zinc mine production increased slightly in 2015 compared to 2014 levels, primarily
 32 owing mostly to the reopening of the Pend Oreille Mine in Washington in late 2014. The mine was expected to
 33 reach full production by yearend 2015. Zinc metal production decreased slightly due to a decline in secondary
 34 production; in 2014, Horsehead closed its smelter in Monaca, PA, while starting up its new recycling facility in
 35 Mooresboro, NC. However, the new facility experienced continued delays in ramp-up efforts due to technical issues
 36 (USGS 2016). Primary zinc production (primary slab zinc) increased by 14 percent in 2015, while, secondary zinc
 37 production in 2015 decreased by 29 percent relative to 2014.

38 Emissions of CO₂ from zinc production in 2015 were estimated to be 0.9 MMT CO₂ Eq. (933 kt CO₂) (see Table
 39 4-89). All 2015 CO₂ emissions resulted from secondary zinc production processes. Emissions from zinc production
 40 in the United States have increased overall since 1990 due to a gradual shift from non-emissive primary production
 41 to emissive secondary production. In 2015, emissions were estimated to be 48 percent higher than they were in
 42 1990.

43 **Table 4-88: Zinc Production (Metric Tons)**

Year	Primary	Secondary
1990	262,704	95,708
2005	191,120	156,000
2011	110,000	138,000
2012	114,000	147,000
2013	106,000	127,000
2014	110,000	70,000
2015	125,000	50,000

1 **Table 4-89: CO₂ Emissions from Zinc Production (MMT CO₂ Eq. and kt)**

Year	MMT CO ₂ Eq.	kt
1990	0.6	632
2005	1.0	1,030
2011	1.3	1,286
2012	1.5	1,486
2013	1.4	1,429
2014	1.0	956
2015	0.9	933

2 **Methodology**

3 The methods used to estimate non-energy CO₂ emissions from zinc production⁵¹ using the electrothermic primary
 4 production and Waelz kiln secondary production processes are based on Tier 1 methods from the *2006 IPCC*
 5 *Guidelines* (IPCC 2006). The Tier 1 equation used to estimate emissions from zinc production is as follows:

6
$$E_{CO_2} = Zn \times EF_{default}$$

7 where,

- 8 E_{CO₂} = CO₂ emissions from zinc production, metric tons
 9 Zn = Quantity of zinc produced, metric tons
 10 EF_{default} = Default emission factor, metric tons CO₂/metric ton zinc produced

11
 12 The Tier 1 emission factors provided by IPCC for Waelz kiln-based secondary production were derived from coke
 13 consumption factors and other data presented in Viklund-White (2000). These coke consumption factors as well as
 14 other inputs used to develop the Waelz kiln emission factors are shown below. IPCC does not provide an emission
 15 factor for electrothermic processes due to limited information; therefore, the Waelz kiln-specific emission factors
 16 were also applied to zinc produced from electrothermic processes. Starting in 2014, refined zinc produced in the
 17 United States used hydrometallurgical processes and is assumed to be non-emissive.

18 For Waelz kiln-based production, IPCC recommends the use of emission factors based on EAF dust consumption, if
 19 possible, rather than the amount of zinc produced since the amount of reduction materials used is more directly
 20 dependent on the amount of EAF dust consumed. Since only a portion of emissive zinc production facilities
 21 consume EAF dust, the emission factor based on zinc production is applied to the non-EAF dust consuming
 22 facilities while the emission factor based on EAF dust consumption is applied to EAF dust consuming facilities.

23 The Waelz kiln emission factor based on the amount of zinc produced was developed based on the amount of
 24 metallurgical coke consumed for non-energy purposes per ton of zinc produced (i.e., 1.19 metric tons coke/metric
 25 ton zinc produced) (Viklund-White 2000), and the following equation:

26
$$EF_{Waelz\ Kiln} = \frac{1.19\ metric\ tons\ coke}{metric\ tons\ zinc} \times \frac{0.85\ metric\ tons\ C}{metric\ tons\ coke} \times \frac{3.67\ metric\ tons\ CO_2}{metric\ tons\ C} = \frac{3.70\ metric\ tons\ CO_2}{metric\ tons\ zinc}$$

27 The Waelz kiln emission factor based on the amount of EAF dust consumed was developed based on the amount of
 28 metallurgical coke consumed per ton of EAF dust consumed (i.e., 0.4 metric tons coke/metric ton EAF dust
 29 consumed) (Viklund-White 2000), and the following equation:

⁵¹ EPA has not integrated aggregated facility-level Greenhouse Gas Reporting Program (GHGRP) information to inform these estimates. The aggregated information (e.g., activity data and emissions) associated with Zinc Production did not meet criteria to shield underlying confidential business information (CBI) from public disclosure.

$$EF_{EAF\ Dust} = \frac{0.4\ \text{metric tons coke}}{\text{metric tons EAF Dust}} \times \frac{0.85\ \text{metric tons C}}{\text{metric tons coke}} \times \frac{3.67\ \text{metric tons CO}_2}{\text{metric tons C}} = \frac{1.24\ \text{metric tons CO}_2}{\text{metric tons EAF Dust}}$$

The total amount of EAF dust consumed by Horsehead at their Waelz kilns was available from Horsehead financial reports for years 2006 through 2015 (Horsehead 2007, 2008, 2010a, 2011, 2012a, 2013, 2014, 2015, and 2016). Consumption levels for 1990 through 2005 were extrapolated using the percentage change in annual refined zinc production at secondary smelters in the United States as provided by the U.S. Geological Survey (USGS) *Minerals Yearbook: Zinc* (USGS 1995 through 2006). The EAF dust consumption values for each year were then multiplied by the 1.24 metric tons CO₂/metric ton EAF dust consumed emission factor to develop CO₂ emission estimates for Horsehead’s Waelz kiln facilities.

The amount of EAF dust consumed by Steel Dust Recycling (SDR) and their total production capacity were obtained from SDR’s facility in Alabama for the years 2011 through 2015 (SDR 2012, 2014, 2015, and 2017). SDR’s facility in Alabama underwent expansion in 2011 to include a second unit (operational since early- to mid-2012). SDR’s facility has been operational since 2008. Annual consumption data for SDR was not publicly available for the years 2008, 2009, and 2010. These data were estimated using data for Horsehead’s Waelz kilns for 2008 through 2010 (Horsehead 2007, 2008, 2010a, 2010b, and 2011). Annual capacity utilization ratios were calculated using Horsehead’s annual consumption and total capacity for the years 2008 through 2010. Horsehead’s annual capacity utilization ratios were multiplied with SDR’s total capacity to estimate SDR’s consumption for each of the years, 2008 through 2010 (SDR 2013).

PIZO Technologies Worldwide LLC’s facility in Arkansas has been operational since 2009. The amount of EAF dust consumed by PIZO’s facility for 2009 through 2015 was not publicly available. EAF dust consumption for PIZO’s facility for 2009 and 2010 were estimated by calculating annual capacity utilization of Horsehead’s Waelz kilns and multiplying this utilization ratio by PIZO’s total capacity (PIZO 2012). EAF dust consumption for PIZO’s facility for 2011 through 2015 were estimated by applying the average annual capacity utilization rates for Horsehead and SDR (Grupo PROMAX) to PIZO’s annual capacity (Horsehead 2012, 2013, 2014, 2015, and 2016; SDR 2012, 2014 and 2017; PIZO 2012, 2014 and 2017). The 1.24 metric tons CO₂/metric ton EAF dust consumed emission factor was then applied to PIZO’s and Steel Dust Recycling’s estimated EAF dust consumption to develop CO₂ emission estimates for those Waelz kiln facilities.

Refined zinc production levels for Horsehead’s Monaca, PA facility (utilizing electrothermic technology) were available from the company for years 2005 through 2013 (Horsehead 2008, 2011, 2012, 2013, and 2014). The Monaca facility was permanently shut down in April 2014 and was replaced by Horsehead’s new facility in Mooresboro, NC. The new facility uses hydrometallurgical process to produce refined zinc products. This process is assumed to be non-emissive. Production levels for 1990 through 2004 were extrapolated using the percentage changes in annual refined zinc production at secondary smelters in the United States as provided by USGS *Minerals Yearbook: Zinc* (USGS 1995 through 2005). The 3.70 metric tons CO₂/metric ton zinc emission factor was then applied to the Monaca facility’s production levels to estimate CO₂ emissions for the facility. The Waelz kiln production emission factor was applied in this case rather than the EAF dust consumption emission factor since Horsehead’s Monaca facility did not consume EAF dust.

Uncertainty and Time-Series Consistency – TO BE UPDATED FOR FINAL INVENTORY REPORT

The uncertainty associated with these estimates is two-fold, relating to activity data and emission factors used.

First, there is uncertainty associated with the amount of EAF dust consumed in the United States to produce secondary zinc using emission-intensive Waelz kilns. The estimate for the total amount of EAF dust consumed in Waelz kilns is based on (1) an EAF dust consumption value reported annually by Horsehead Corporation as part of its financial reporting to the Securities and Exchange Commission (SEC), and (2) an EAF dust consumption value obtained from the Waelz kiln facility operated in Alabama by Steel Dust Recycling LLC. Since actual EAF dust consumption information is not available for PIZO’s facility (2009 through 2010) and SDR’s facility (2008 through 2010), the amount is estimated by multiplying the EAF dust recycling capacity of the facility (available from the company’s website) by the capacity utilization factor for Horsehead Corporation (which is available from Horsehead’s financial reports). Also, the EAF dust consumption for PIZO’s facility for 2011 through 2013 was

1 estimated by multiplying the average capacity utilization factor developed from Horsehead Corp. and SDR's annual
 2 capacity utilization rates by PIZO's EAF dust recycling capacity. Therefore, there is uncertainty associated with the
 3 assumption used to estimate PIZO and SDR's annual EAF dust consumption values (except SDR's EAF dust
 4 consumption for 2011 through 2013, which were obtained from SDR's recycling facility in Alabama).

5 Second, there is uncertainty associated with the emission factors used to estimate CO₂ emissions from secondary
 6 zinc production processes. The Waelz kiln emission factors are based on materials balances for metallurgical coke
 7 and EAF dust consumed as provided by Viklund-White (2000). Therefore, the accuracy of these emission factors
 8 depend upon the accuracy of these materials balances. Data limitations prevented the development of emission
 9 factors for the electrothermic process. Therefore, emission factors for the Waelz kiln process were applied to both
 10 electrothermic and Waelz kiln production processes.

11 The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-90. Zinc production CO₂
 12 emissions from 2015 were estimated to be between 0.8 and 1.2 MMT CO₂ Eq. at the 95 percent confidence level.
 13 This indicates a range of approximately 19 percent below and 21 percent above the emission estimate of 1.0 MMT
 14 CO₂ Eq.

15 **Table 4-90: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Zinc**
 16 **Production (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a (%)			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Zinc Production	CO ₂	1.0	0.8	1.2	-19%	+21%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

17 Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990
 18 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 19 above.

20 Planned Improvements

21 Pending resources and prioritization of improvements for more significant sources, EPA will continue to evaluate
 22 and analyze data reported under EPA's GHGRP that would be useful to improve the emission estimates and
 23 category specific QC for the Zinc Production source category, in particular considering completeness of reported
 24 zinc production given the reporting threshold. Given the small number of facilities in the US, particular attention
 25 will be made to risks for disclosing CBI and ensuring time series consistency of the emissions estimates presented in
 26 future Inventory reports, consistent with IPCC and UNFCCC guidelines. This is required as the facility-level
 27 reporting data from EPA's GHGRP, with the program's initial requirements for reporting of emissions in calendar
 28 year 2010, are not available for all inventory years (i.e., 1990 through 2009) as required for this Inventory. In
 29 implementing improvements and integration of data from EPA's GHGRP, the latest guidance from the IPCC on the
 30 use of facility-level data in national inventories will be relied upon.⁵² EPA is still assessing the possibility of
 31 including this planned improvement in future Inventory reports.

⁵² See <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

4.22 Semiconductor Manufacture (IPCC Source Category 2E1)

The semiconductor industry uses multiple greenhouse gases (GHGs) in its manufacturing processes. These include long-lived fluorinated greenhouse gases used for plasma etching and chamber cleaning, fluorinated heat transfer fluids used for temperature control and other applications, and nitrous oxide (N₂O) used to produce thin films through chemical vapor deposition.

The gases most commonly employed in plasma etching and chamber cleaning are trifluoromethane (HFC-23 or CHF₃), perfluoromethane (CF₄), perfluoroethane (C₂F₆), nitrogen trifluoride (NF₃), and sulfur hexafluoride (SF₆), although other fluorinated compounds such as perfluoropropane (C₃F₈) and perfluorocyclobutane (c-C₄F₈) are also used. The exact combination of compounds is specific to the process employed.

A single 300 mm silicon wafer that yields between 400 to 600 semiconductor products (devices or chips) may require more than 100 distinct fluorinated-gas-using process steps, principally to deposit and pattern dielectric films. Plasma etching (or patterning) of dielectric films, such as silicon dioxide and silicon nitride, is performed to provide pathways for conducting material to connect individual circuit components in each device. The patterning process uses plasma-generated fluorine atoms, which chemically react with exposed dielectric film to selectively remove the desired portions of the film. The material removed as well as undissociated fluorinated gases flow into waste streams and, unless emission abatement systems are employed, into the atmosphere. Plasma enhanced chemical vapor deposition (PECVD) chambers, used for depositing dielectric films, are cleaned periodically using fluorinated and other gases. During the cleaning cycle the gas is converted to fluorine atoms in plasma, which etches away residual material from chamber walls, electrodes, and chamber hardware. Undissociated fluorinated gases and other products pass from the chamber to waste streams and, unless abatement systems are employed, into the atmosphere.

In addition to emissions of unreacted gases, some fluorinated compounds can also be transformed in the plasma processes into different fluorinated compounds which are then exhausted, unless abated, into the atmosphere. For example, when C₂F₆ is used in cleaning or etching, CF₄ is generated and emitted as a process by-product. In some cases, emissions of the by-product gas can rival or even exceed emissions of the input gas, as is the case for NF₃ used in remote plasma chamber cleaning, which generates CF₄ as a by-product.

Besides dielectric film etching and PECVD chamber cleaning, much smaller quantities of fluorinated gases are used to etch polysilicon films and refractory metal films like tungsten.

N₂O is used in manufacturing semiconductor devices to produce thin films by CVD and nitridation processes as well as for N-doping of compound semiconductors and reaction chamber conditioning (Doering 2000).

Liquid perfluorinated compounds are also used as heat transfer fluids (HTFs) for temperature control, device testing, cleaning substrate surfaces and other parts, and soldering in certain types of semiconductor manufacturing production processes. Leakage and evaporation of these fluids during use is a source of fluorinated gas emissions (U.S. EPA 2006). Unweighted HTF emissions consist primarily of perfluorinated amines, hydrofluoroethers, perfluoropolyethers, and perfluoroalkylmorpholines. With the exception of the hydrofluoroethers, all of these compounds are very long-lived in the atmosphere and have GWPs near 10,000.⁵³

For 2015, total GWP-weighted emissions of all fluorinated greenhouse gases and nitrous oxide from deposition, etching, and chamber cleaning processes in the U.S. semiconductor industry were estimated to be 5.0 MMT CO₂ Eq. Total emissions of all greenhouse gases other than HTFs are presented in Table 4-91 and Table 4-92 below for the

⁵³ The GWP of PFPME, a perfluoropolyether used as an HTF, is included in the Fourth Assessment Report with a value of 10,300. The GWPs of the perfluorinated amines and perfluoroalkylmorpholines that are used as HTFs have not been evaluated in the peer-reviewed literature. However, evaluations by the manufacturer indicate that their GWPs are near 10,000 (78 FR 20632), which is expected given that these compounds are both saturated and fully fluorinated. EPA assigns a default GWP of 10,000 to compounds that are both saturated and fully fluorinated and that do not have chemical-specific GWPs in either the Fourth or the Fifth Assessment Reports.

years 1990, 2005, and the period 2010 to 2015. (HTF emissions are presented separately, as discussed below.) The rapid growth of this industry and the increasing complexity (growing number of layers)⁵⁴ of semiconductor products led to an increase in emissions of 153 percent between 1990 and 1999, when emissions peaked at 9.1 MMT CO₂ Eq. Emissions began to decline after 1999, declining by 45 percent between 1999 and 2015. Together, industrial growth, adoption of emissions reduction technologies (including but not limited to abatement technologies), and shifts in gas usages resulted in a net increase in emissions of 40 percent between 1990 and 2015.

In 2010, the industry was still recovering from slowed economic activity which began in 2008. Between 2010 and 2011 fluorinated gas and N₂O emissions increased by 24 percent; reductions in emissions of 9 percent were then observed between both 2011 and 2012, and 2012 and 2013. Emissions increased in 2014, by 24 percent compared to 2013, and stayed similar in 2015, decreasing by less than 1 percent compared to 2014. As discussed below, this apparent increase between 2013 and 2014 is likely to be an artifact of a change in the emission factors applied by facilities that report their emissions to EPA under the Greenhouse Gas Reporting Program (GHGRP).

Facility emissions of HTFs from semiconductor manufacturing are reported to EPA under the GHGRP, and are available for the years 2011 through 2015. These emissions are provided for informational purposes and not included in the Inventory totals presented in Table 4-91. It is important to note that the HTF emissions presented in these tables represent a sum of HTF emissions, in CO₂ Eq., from facilities that report under the GHGRP, or only those facilities whose emissions exceed 25,000 metric tons annually. The HTF emissions in 2011 were 0.75 MMT CO₂ Eq., with a high of 0.92 MMT CO₂ Eq. in 2012. Emissions in 2013 were the lowest at 0.62 MMT CO₂ Eq. while the emissions in 2014 and 2015 are comparable at 0.79 MMT CO₂ Eq. and 0.76 MMT CO₂ Eq. respectively. Emissions from one facility contribute significantly to the high emissions in 2012, while the decrease in emissions of the same facility contributes to the lowest emissions in 2013. Emissions in 2014 and 2015 are slightly higher due to a higher number of total reporting facilities. These new facilities represent 1.4 percent of total HTF emissions in 2014, and 1.7 percent in 2015. Additionally, an analysis of the available data reported to the GHGRP indicates that HTF emissions account for anywhere between 13 percent and 17 percent of total annual emissions (F-GHG, N₂O and HTFs) from semiconductor manufacturing.⁵⁵

Table 4-91: PFC, HFC, SF₆, NF₃, and N₂O Emissions from Semiconductor Manufacture (MMT CO₂ Eq.)

Year	1990	2005	2010	2011	2012	2013	2014	2015
CF ₄	0.8	1.1	1.1	1.4	1.3	1.2	1.6	1.5

<i>HTFs^a</i>	<i>0.0</i>	<i>0.0</i>	<i>0.0</i>	<i>0.7</i>	<i>0.9</i>	<i>0.6</i>	<i>0.8</i>	<i>0.8</i>

+ Does not exceed 0.05 MMT CO₂ Eq.

^a The HTF emissions from 1990 to 2010 are not estimated and reported as 0. HTF use in semiconductor manufacturing began in early 2000s, and by 2005 started to penetrate applications in electronics manufacturing (U.S. EPA 2006). Emissions are not estimated for those years due to lack of reliable emission factors and activity data for HTFs.

⁵⁴ Complexity is a term denoting the circuit required to connect the active circuit elements (transistors) on a chip. Increasing miniaturization, for the same chip size, leads to increasing transistor density, which, in turn, requires more complex interconnections between those transistors. This increasing complexity is manifested by increasing the levels (i.e., layers) of wiring, with each wiring layer requiring fluorinated gas usage for its manufacture.

⁵⁵ Emissions data for HTFs (in tons of gas) from the semiconductor industry from 2011 through 2015 were obtained from the EPA GHGRP annual facility emissions reports.

Note: Totals may not sum due to independent rounding. HTF emissions presented represent the GHGRP-reporting facilities only, or approximately 97 percent of the U.S. industry, based on total manufactured layer area in 2015.

1 **Table 4-92: PFC, HFC, SF₆, NF₃, and N₂O Emissions from Semiconductor Manufacture (kt)**

Year	1990	2005	2010	2011	2012	2013	2014	2015

2 Methodology

3 Emissions are based on data reported through Subpart I, Electronics Manufacture, of EPA’s GHGRP, Partner
 4 reported emissions data received through the EPA’s PFC⁵⁶ Reduction/Climate Partnership, EPA’s PFC Emissions
 5 Vintage Model (PEVM)—a model that estimates industry emissions in the absence of emission control strategies
 6 (Burton and Beizaie 2001),⁵⁷ and estimates of industry activity (i.e., total manufactured layer area). The availability
 7 and applicability of reported emissions data from the EPA Partnership and EPA’s GHGRP, and activity data differs
 8 across the 1990 through 2015 time series. Consequently, fluorinated greenhouse gas (F-GHG) emissions from
 9 semiconductor manufacturing were estimated using six distinct methods, one each for the periods 1990 through
 10 1994, 1995 through 1999, 2000 through 2006, 2007 through 2010, 2011 through 2012 and 2015, and 2013 through
 11 2014. Nitrous oxide emissions were estimated using four distinct methods, one each for the period 1990 through
 12 1994, 1995 through 2010, 2011 through 2012 and 2015, and 2013 through 2014.

13 1990 through 1994

14 From 1990 through 1994, Partnership data were unavailable and emissions were modeled using PEVM (Burton and
 15 Beizaie 2001).⁵⁸ The 1990 to 1994 emissions are assumed to be uncontrolled, since reduction strategies such as
 16 chemical substitution and abatement were yet to be developed.

17 PEVM is based on the recognition that fluorinated greenhouse gas emissions from semiconductor manufacturing
 18 vary with: (1) the number of layers that comprise different kinds of semiconductor devices, including both silicon
 19 wafer and metal interconnect layers, and (2) silicon consumption (i.e., the area of semiconductors produced) for
 20 each kind of device. The product of these two quantities, Total Manufactured Layer Area (TMLA), constitutes the
 21 activity data for semiconductor manufacturing. PEVM also incorporates an emission factor that expresses emissions
 22 per unit of manufactured layer-area. Emissions are estimated by multiplying TMLA by this emission factor.

⁵⁶ In the context of the EPA Partnership and PEVM, PFC refers to perfluorocompounds, not perfluorocarbons.

⁵⁷ A Partner refers to a participant in the U.S. EPA PFC Reduction/Climate Partnership for the Semiconductor Industry. Through a Memorandum of Understanding (MoU) with the EPA, Partners voluntarily reported their PFC emissions to the EPA by way of a third party, which aggregated the emissions through 2010.

⁵⁸ Various versions of the PEVM exist to reflect changing industrial practices. From 1990 to 1994 emissions estimates are from PEVM v1.0, completed in September 1998. The emission factor used to estimate 1990 to 1994 emissions is an average of the 1995 and 1996 emissions factors, which were derived from Partner reported data for those years.

1 PEVM incorporates information on the two attributes of semiconductor devices that affect the number of layers: (1)
2 linewidth technology (the smallest manufactured feature size),⁵⁹ and (2) product type (discrete, memory or logic).⁶⁰
3 For each linewidth technology, a weighted average number of layers is estimated using VLSI product-specific
4 worldwide silicon demand data in conjunction with complexity factors (i.e., the number of layers per Integrated
5 Circuit (IC) specific to product type (Burton and Beizaie 2001; ITRS 2007). PEVM derives historical consumption
6 of silicon (i.e., square inches) by linewidth technology from published data on annual wafer starts and average wafer
7 size (VLSI Research, Inc. 2012).

8 The emission factor in PEVM is the average of four historical emission factors, each derived by dividing the total
9 annual emissions reported by the Partners for each of the four years between 1996 and 1999 by the total TMLA
10 estimated for the Partners in each of those years. Over this period, the emission factors varied relatively little (i.e.,
11 the relative standard deviation for the average was 5 percent). Since Partners are believed not to have applied
12 significant emission reduction measures before 2000, the resulting average emission factor reflects uncontrolled
13 emissions. The emission factor is used to estimate world uncontrolled emissions using publicly-available data on
14 world silicon consumption.

15 As it was assumed for this time period that there was no consequential adoption of fluorinated-gas-reducing
16 measures, a fixed distribution of fluorinated-gas use was assumed to apply to the entire U.S. industry to estimate
17 gas-specific emissions. This distribution was based upon the average fluorinated-gas purchases made by
18 semiconductor manufacturers during this period and the application of IPCC default emission factors for each gas
19 (Burton and Beizaie 2001).

20 To estimate N₂O emissions, it is assumed the proportion of N₂O emissions estimated for 1995 (discussed below)
21 remained constant for the period of 1990 through 1994.

22 **1995 through 1999**

23 For 1995 through 1999, total U.S. emissions were extrapolated from the total annual emissions reported by the
24 Partners (1995 through 1999). Partner-reported emissions are considered more representative (e.g., in terms of
25 capacity utilization in a given year) than PEVM estimated emissions, and are used to generate total U.S. emissions
26 when applicable. The emissions reported by the Partners were divided by the ratio of the total capacity of the plants
27 operated by the Partners and the total capacity of all of the semiconductor plants in the United States; this ratio
28 represents the share of capacity attributable to the Partnership. This method assumes that Partners and non-Partners
29 have identical capacity utilizations and distributions of manufacturing technologies. Plant capacity data is contained
30 in the World Fab Forecast (WFF) database and its predecessors, which is updated quarterly (Semiconductor
31 Equipment and Materials Industry 2012 and 2013). Gas-specific emissions were estimated using the same method as
32 for 1990 through 1994.

33 For this time period, the N₂O emissions were estimated using an emission factor that is applied to the annual, total
34 U.S. TMLA manufactured. The emission factor was developed using a regression-through-the-origin (RTO) model:
35 GHGRP reported N₂O emissions were regressed against the corresponding TMLA of facilities that reported no use
36 of abatement systems. Details on EPA's GHGRP reported emissions and development of emission factor using the
37 RTO model are presented in the 2011 through 2012 section. The total U.S. TMLA was estimated using PEVM.

⁵⁹ By decreasing features of Integrated Circuit components, more components can be manufactured per device, which increases its functionality. However, as those individual components shrink it requires more layers to interconnect them to achieve the functionality. For example, a microprocessor manufactured with 65 nm feature sizes might contain as many as 1 billion transistors and require as many as 11 layers of component interconnects to achieve functionality, while a device manufactured with 130 nm feature size might contain a few hundred million transistors and require 8 layers of component interconnects (ITRS 2007).

⁶⁰ Memory devices manufactured with the same feature sizes as microprocessors (a logic device) require approximately one-half the number of interconnect layers, whereas discrete devices require only a silicon base layer and no interconnect layers (ITRS 2007). Since discrete devices did not start using PFCs appreciably until 2004, they are only accounted for in the PEVM emissions estimates from 2004 onwards.

2000 through 2006

Emissions for the years 2000 through 2006—the period during which Partners began the consequential application of fluorinated greenhouse gas-reduction measures—were estimated using a combination of Partner-reported emissions and adjusted PEVM modeled emissions. The emissions reported by Partners for each year were accepted as the quantity emitted from the share of the industry represented by those Partners. Remaining emissions, those from non-Partners, were estimated using PEVM, with one change. To ensure time series consistency and to reflect the increasing use of remote clean technology (which increases the efficiency of the production process while lowering emissions of fluorinated greenhouse gases), the average non-Partner emission factor (PEVM emission factor) was assumed to begin declining gradually during this period. Specifically, the non-Partner emission factor for each year was determined by linear interpolation, using the end points of 1999 (the original PEVM emission factor) and 2011 (a new emission factor determined for the non-Partner population based on GHGRP-reported data, described below).

The portion of the U.S. total attributed to non-Partners is obtained by multiplying PEVM’s total U.S. emissions figure by the non-Partner share of U.S. total silicon capacity for each year as described above.⁶¹ Gas-specific emissions from non-Partners were estimated using linear interpolation of gas-specific emission distribution of 1999 (assumed same as total U.S. Industry in 1994) and 2011 (calculated from a subset of non-Partner facilities from GHGRP reported emissions data). Annual updates to PEVM reflect published figures for actual silicon consumption from VLSI Research, Inc., revisions and additions to the world population of semiconductor manufacturing plants, and changes in IC fabrication practices within the semiconductor industry (see ITRS 2008 and Semiconductor Equipment and Materials Industry 2011).^{62,63,64}

The N₂O emissions were estimated using the same methodology as the 1995 through 1999 methodology.

2007 through 2010

For the years 2007 through 2010, emissions were also estimated using a combination of Partner reported emissions and adjusted PEVM modeled emissions to provide estimates for non-Partners; however, two improvements were made to the estimation method employed for the previous years in the time series. First, the 2007 through 2010 emission estimates account for the fact that Partners and non-Partners employ different distributions of manufacturing technologies, with the Partners using manufacturing technologies with greater transistor densities and

⁶¹ This approach assumes that the distribution of linewidth technologies is the same between Partners and non-Partners. As discussed in the description of the method used to estimate 2007 emissions, this is not always the case.

⁶² Special attention was given to the manufacturing capacity of plants that use wafers with 300 mm diameters because the actual capacity of these plants is ramped up to design capacity, typically over a 2–3 year period. To prevent overstating estimates of partner-capacity shares from plants using 300 mm wafers, *design* capacities contained in WFF were replaced with estimates of *actual installed* capacities for 2004 published by Citigroup Smith Barney (2005). Without this correction, the partner share of capacity would be overstated, by approximately 5 percent. For perspective, approximately 95 percent of all new capacity additions in 2004 used 300 mm wafers, and by year-end those plants, on average, could operate at approximately 70 percent of the design capacity. For 2005, actual installed capacities were estimated using an entry in the World Fab Watch database (April 2006 Edition) called “wafers/month, 8-inch equivalent,” which denoted the actual installed capacity instead of the fully-ramped capacity. For 2006, actual installed capacities of new fabs were estimated using an average monthly ramp rate of 1100 wafer starts per month (wspm) derived from various sources such as semiconductor fabtech, industry analysts, and articles in the trade press. The monthly ramp rate was applied from the first-quarter of silicon volume (FQSV) to determine the average design capacity over the 2006 period.

⁶³ In 2006, the industry trend in co-ownership of manufacturing facilities continued. Several manufacturers, who are Partners, now operate fabs with other manufacturers, who in some cases are also Partners and in other cases are not Partners. Special attention was given to this occurrence when estimating the Partner and non-Partner shares of U.S. manufacturing capacity.

⁶⁴ Two versions of PEVM are used to model non-Partner emissions during this period. For the years 2000 to 2003 PEVM v3.2.0506.0507 was used to estimate non-Partner emissions. During this time, discrete devices did not use PFCs during manufacturing and therefore only memory and logic devices were modeled in the PEVM v3.2.0506.0507. From 2004 onwards, discrete device fabrication started to use PFCs, hence PEVM v4.0.0701.0701, the first version of PEVM to account for PFC emissions from discrete devices, was used to estimate non-Partner emissions for this time period.

1 therefore greater numbers of layers.⁶⁵ Second, the scope of the 2007 through 2010 estimates was expanded relative
2 to the estimates for the years 2000 through 2006 to include emissions from research and development (R&D) fabs.
3 This additional enhancement was feasible through the use of more detailed data published in the WFF. PEVM
4 databases were updated annually as described above. The published world average capacity utilization for 2007
5 through 2010 was used for production fabs, while for R&D fabs a 20 percent figure was assumed (SIA 2009).

6 In addition, publicly-available actual utilization data was used to account for differences in fab utilization for
7 manufacturers of discrete and IC products for 2010 emissions for non-Partners. The Semiconductor Capacity
8 Utilization (SICAS) Reports from SIA provides the global semiconductor industry capacity and utilization,
9 differentiated by discrete and IC products (SIA, 2009 through 2011). PEVM estimates were adjusted using
10 technology-weighted capacity shares that reflect the relative influence of different utilization. Gas-specific emissions
11 for non-Partners were estimated using the same method as for 2000 through 2006.

12 The N₂O emissions were estimated using the same methodology as the 1995 through 1999 methodology.

13 **2011 through 2012 and 2015**

14 The fifth method for estimating emissions from semiconductor manufacturing covers the period 2011 through 2012
15 and 2015. This methodology does not include emissions of non-reporting populations for the years 2013 and 2014
16 because for the non-reporting population, emission factors and facility-specific production were not estimated. The
17 emissions for these time periods are estimated using a sixth method described below. This methodology differs from
18 previous years because the EPA's Partnership with the semiconductor industry ended (in 2010) and reporting under
19 EPA's GHGRP began. Manufacturers whose estimated uncontrolled emissions equal or exceed 25,000 MT CO₂ Eq.
20 per year (based on default F-GHG-specific emission factors and total capacity in terms of substrate area) are
21 required to report their emissions to EPA. This population of reporters to EPA's GHGRP included both historical
22 Partners of EPA's PFC Reduction/Climate Partnership as well as non-Partners. In EPA's GHGRP, the population of
23 non-Partner facilities also included manufacturers that use GaAs technology in addition to Si technology.⁶⁶
24 Emissions from the population of manufacturers that were below the reporting threshold were also estimated for this
25 time period using EPA-developed emission factors and estimates of facility-specific production obtained from WFF.
26 Inventory totals reflect the emissions from both populations.

27 Under EPA's GHGRP, semiconductor manufacturing facilities report emissions of F-GHGs used in etch and clean
28 processes as well as emissions of fluorinated heat transfer fluids. (Fluorinated heat transfer fluids are used to control
29 process temperatures, thermally test devices, and clean substrate surfaces, among other applications.) They also
30 report N₂O emissions from CVD and other processes. The F-GHGs and N₂O were aggregated, by gas, across all
31 semiconductor manufacturing GHGRP reporters to calculate gas-specific emissions for the GHGRP-reporting
32 segment of the U.S. industry. At this time, emissions that result from heat transfer fluid use are not included in the
33 total emission estimates from semiconductor manufacturing, though GHGRP reported emissions have been
34 compiled and presented for informational purposes in Table 4-91.

35 For the segment of the semiconductor industry that is below EPA's GHGRP reporting threshold, and for R&D
36 facilities, which are not covered by EPA's GHGRP, emission estimates are based on EPA-developed emission
37 factors for the F-GHGs and N₂O and estimates of manufacturing activity. The new emission factors (in units of mass
38 of CO₂ Eq./TMLA [MSI]) are based on the emissions reported by facilities under EPA's GHGRP and TMLA
39 estimates for these facilities from the WFF (SEMI 2012, SEMI 2013, and SEMI 2016). In a refinement of the
40 method used in prior years to estimate emissions for the non-Partner population, different emission factors were
41 developed for different subpopulations of fabs, one for facilities that manufacture devices on Si wafers and one for
42 facilities that manufacture on GaAs wafers. An analysis of the emission factors of reporting fabs showed that the

⁶⁵ EPA considered applying this change to years before 2007, but found that it would be difficult due to the large amount of data (i.e., technology-specific global and non-Partner TMLA) that would have to be examined and manipulated for each year. This effort did not appear to be justified given the relatively small impact of the improvement on the total estimate for 2007 and the fact that the impact of the improvement would likely be lower for earlier years because the estimated share of emissions accounted for by non-Partners is growing as Partners continue to implement emission-reduction efforts.

⁶⁶ GaAs and Si technologies refer to the wafer on which devices are manufactured, which use the same PFCs but in different ways.

1 characteristics that had the largest impacts on emission factors were the substrate (i.e., Si or GaAs) used at the fab,
2 whether the fab contained R&D activities, and whether the fab reported using point-of-use fluorinated greenhouse
3 gas abatement.⁶⁷ For each of these groups, a subpopulation-specific emission factor was obtained using a
4 regression-through-the-origin (RTO) model: facility-reported aggregate emissions of seven F-GHGs (CF₄, C₂F₆,
5 C₃F₈, C₄F₈, CHF₃, SF₆ and NF₃)⁶⁸ were regressed against the corresponding TMLA to estimate an aggregate F-GHG
6 emissions factor (CO₂ Eq./MSI TMLA), and facility-reported N₂O emissions were regressed against the
7 corresponding TMLA to estimate a N₂O emissions factor (CO₂ Eq./MSI TMLA). For each subpopulation, the slope
8 of the RTO model is the emission factor for that subpopulation. To estimate emissions from fabs that are solely
9 doing research and development (R&D) or are Pilot fabs (i.e., fabs that are excluded from subpart I reporting
10 requirements), emission factors were estimated based on GHGRP reporting fabs containing R&D activities. EPA
11 applied a scaling factor of 1.15 to the slope of the RTO model to estimate the emission factor applicable to the non-
12 reporting fabs that are only R&D or Pilot fabs. This was done as R&D activities lead to use of more F-GHGs and
13 N₂O for development of chips that are not counted towards the final estimated TMLA. Hence, it is assumed that the
14 fabs with only R&D activities use 15 percent more F-GHGs and N₂O per TMLA.

15 For 2011, 2012 and 2015, estimates of TMLA relied on the capacity utilization of the fabs published by the U.S.
16 Census Bureau's Historical Data Quarterly Survey of Plant Capacity Utilization (USCB 2011, 2012, 2016). Similar
17 to the assumption for 2007 through 2010, facilities with only R&D activities were assumed to utilize only 20 percent
18 of their manufacturing capacity. All other facilities in the United States are assumed to utilize the average percent of
19 the manufacturing capacity without distinguishing whether fabs produce discrete products or logic products.

20 Non-reporting fabs were then broken out into similar subpopulations. Information on the technology and R&D
21 activities of non-reporting fabs was available through the WFF. Information on the use of point-of-use abatement by
22 non-reporting fabs was not available; thus, EPA conservatively assumed that non-reporting facilities did not use
23 point-of-use abatement. The appropriate emission factor was applied to the total TMLA of each subpopulation of
24 non-reporting facilities to estimate the GWP-weighted emissions of that subpopulation.

25 Gas-specific, GWP-weighted emissions for each subpopulation of non-reporting facilities were estimated using the
26 corresponding reported distribution of gas-specific, GWP-weighted emissions from which the aggregate emission
27 factors, based on GHGRP reported data, were developed. Estimated in this manner, the non-reporting population
28 accounted for 10, 11, and 6 percent of U.S. emissions in 2011, 2012, and 2015, respectively. EPA's GHGRP-
29 reported emissions and the calculated non-reporting population emissions are summed to estimate the total
30 emissions from semiconductor manufacturing.

31 The methodology used for this time period included emissions from facilities employing Si- and GaAs-using
32 technologies. The use of GaAs technology became evident via analysis of GHGRP emissions and WFF data.
33 However, no adjustment of pre-2011 emissions was made because (1) the use of these technologies appears
34 relatively new, (2) in the aggregate these emissions make a relatively small contribution to total industry emissions
35 (i.e., 3 percent in 2015), and (3) it would require a large effort to retroactively adjust pre-2011 emissions.

36 **2013 through 2014**

37 For the years 2013 through 2014, as for 2011, 2012, and 2015, F-GHG and N₂O emissions data received through
38 EPA's GHGRP were aggregated, by gas, across all semiconductor-manufacturing GHGRP reporters to calculate
39 gas-specific emissions for the GHGRP-reporting segment of the U.S. industry. An updated methodology that does
40 not depend on the WFF derived activity data was used to estimate emissions for the segment of the industry that are
41 not covered by EPA's GHGRP. For the facilities that did not report to the GHGRP (i.e., which are below EPA's
42 GHGRP reporting threshold or are R&D facilities), emissions were estimated based on the proportion of total U.S.
43 emissions attributed to non-reporters for 2011, 2012 and 2015. EPA first estimated this proportion for both F-GHGs
44 and N₂O for 2011, 2012, and 2015, resulting in one proportion for F-GHGs and one for N₂O, and then applied the
45 average of these years' proportions to the 2013 and 2014 GHGRP reported emissions to estimate the non-reporters'

⁶⁷ For the non-reporting segment of the industry using GaAs technology, emissions were estimated only for those fabs that manufactured the same products as manufactured by reporters. The products manufactured were categorized as discrete (emissions did not scale up with decreasing feature size).

⁶⁸ Only seven gases were aggregated because inclusion of F-GHGs that are not reported in the inventory results in overestimation of emission factor that is applied to the various non-reporting subpopulations.

1 emissions. Fluorinated gas-specific, GWP-weighted emissions for non-reporters were estimated using the
2 corresponding reported distribution of gas-specific, GWP-weighted emissions reported through EPA’s GHGRP for
3 2013 and 2014 respectively.

4 **Data Sources**

5 GHGRP reporters, which consist of EPA Partners and non-Partners, estimated their emissions using a default
6 emission factor method established by EPA. Like the Tier 2b Method in the *2006 IPCC Guidelines*, this method
7 uses different emission and by-product generation factors for different F-GHGs and process types, but it goes
8 beyond the Tier 2b Method by requiring use of updated factors for different wafer sizes (i.e., 300 mm vs. 150 and
9 200 mm) and CVD clean subtypes (in situ thermal, in situ thermal, and remote plasma). Starting with 2014 reported
10 emissions, EPA’s GHGRP required semiconductor manufacturers to apply updated emission factors to estimate their
11 F-GHG emissions (40 CFR Part 98). For the years 2011 to 2013 reported emissions, semiconductor manufacturers
12 used older emission factors to estimate their F-GHG Emissions (Federal Register / Vol. 75, No. 230 / Wednesday,
13 December 1, 2010, 74829). GHGRP-reporting facilities are estimated to have accounted for about 92 percent of F-
14 GHG emissions and 95 percent of N₂O emissions from U.S. semiconductor manufacturing between 2011 and 2015.
15 Historically, partners estimated and reported their emissions using a range of methods and uneven documentation. It
16 is assumed that most Partners used a method at least as accurate as the IPCC’s Tier 2a Methodology, recommended
17 in the *2006 IPCC Guidelines*. Partners are estimated to have accounted for between 56 and 79 percent of F-GHG
18 emissions from U.S. semiconductor manufacturing between 1995 and 2010, with the percentage declining in recent
19 years as Partners increasingly implemented abatement measures. Estimates of operating plant capacities and
20 characteristics for Partners and non-Partners were derived from the Semiconductor Equipment and Materials
21 Industry (SEMI) WFF (formerly World Fab Watch) database (1996 through 2012 and 2015) (e.g., Semiconductor
22 Materials and Equipment Industry, 2016). Actual worldwide capacity utilizations for 2008 through 2010 were
23 obtained from Semiconductor International Capacity Statistics (SICAS) (SIA 2009 through 2011). Estimates of the
24 number of layers for each linewidth was obtained from International Technology Roadmap for Semiconductors:
25 2013 Edition (Burton and Beizaie 2001; ITRS 2007; ITRS 2008; ITRS 2011; ITRS 2013). PEVM utilized the WFF,
26 SICAS, and ITRS, as well as historical silicon consumption estimates published by VLSI. Actual quarterly U.S.
27 capacity utilizations for 2011, 2012 and 2015 were obtained from the U.S. Census Bureau’s Historical Data
28 Quarterly Survey of Plant Capacity Utilization (USCB 2011; 2012; 2015).

29 **Uncertainty and Time-Series Consistency**

30 A quantitative uncertainty analysis of this source category was performed using the IPCC-recommended Approach 2
31 uncertainty estimation methodology, the Monte Carlo Stochastic Simulation technique. The equation used to
32 estimate uncertainty is:

$$33 \quad \text{Total Emissions (E}_T\text{)} = \text{GHGRP Reported F-GHG Emissions (E}_{R,\text{F-GHG}}\text{)} + \text{Non-Reporters' Estimated F-GHG} \\ 34 \quad \text{Emissions (E}_{NR,\text{F-GHG}}\text{)} + \text{GHGRP Reported N}_2\text{O Emissions (E}_{R,\text{N}_2\text{O}}\text{)} + \text{Non-Reporters' Estimated N}_2\text{O Emissions} \\ 35 \quad \text{(E}_{NR,\text{N}_2\text{O}}\text{)}$$

36 where E_R and E_{NR} denote totals for the indicated subcategories of emissions for F-GHG and N₂O, respectively.

37 The uncertainty in E_T presented in Table 4-93 below results from the convolution of four distributions of emissions,
38 each reflecting separate estimates of possible values of E_{R,F-GHG}, E_{R,N₂O}, E_{NR,F-GHG}, and E_{NR,N₂O}. The approach and
39 methods for estimating each distribution and combining them to arrive at the reported 95 percent confidence interval
40 (CI) are described in the remainder of this section.

41 The uncertainty estimate of E_{R,F-GHG}, or GHGRP-reported F-GHG emissions, is developed based on gas-specific
42 uncertainty estimates of emissions for two industry segments, one processing 200 mm wafers and one processing
43 300 mm wafers. Uncertainties in emissions for each gas and industry segment were developed during the assessment
44 of emission estimation methods for the subpart I GHGRP rulemaking in 2012 (see *Technical Support for*
45 *Modifications to the Fluorinated Greenhouse Gas Emission Estimation Method Option for Semiconductor Facilities*

1 *under Subpart I, docket EPA–HQ–OAR–2011–0028*).⁶⁹ The 2012 analysis did not take into account the use of
2 abatement. For the industry segment that processed 200 mm wafers, estimates of uncertainties at a 95 percent CI
3 ranged from ±29 percent for C₃F₈ to ±10 percent for CF₄. For the corresponding 300 mm industry segment,
4 estimates of the 95 percent CI ranged from ±36 percent for C₄F₈ to ±16 percent for CF₄. These gas and wafer-
5 specific uncertainty estimates are applied to the total emissions of the facilities that did not abate emissions as
6 reported under EPA’s GHGRP.

7 For those facilities reporting abatement of emissions under EPA’s GHGRP, estimates of uncertainties for the no
8 abatement industry segments are modified to reflect the use of full abatement (abatement of *all* gases from *all*
9 cleaning and etching equipment) and partial abatement. These assumptions used to develop uncertainties for the
10 partial and full abatement facilities are identical for 200 mm and 300 mm wafer processing facilities. For all
11 facilities reporting gas abatement, a triangular distribution of destruction or removal efficiency is assumed for each
12 gas. The triangular distributions range from an asymmetric and highly uncertain distribution of zero percent
13 minimum to 90 percent maximum with 70 percent most likely value for CF₄ to a symmetric and less uncertain
14 distribution of 85 percent minimum to 95 percent maximum with 90 percent most likely value for C₄F₈, NF₃, and
15 SF₆. For facilities reporting partial abatement, the distribution of fraction of the gas fed through the abatement
16 device, for each gas, is assumed to be triangularly distributed as well. It is assumed that no more than 50 percent of
17 the gases area abated (i.e., the maximum value) and that 50 percent is the most likely value and the minimum is zero
18 percent. Consideration of abatement then resulted in four additional industry segments, two 200-mm wafer-
19 processing segments (one fully and one partially abating each gas) and two 300-mm wafer-processing segment (one
20 fully and the other partially abating each gas). Gas-specific emission uncertainties were estimated by convolving the
21 distributions of unabated emissions with the appropriate distribution of abatement efficiency for fully and partially
22 abated facilities using a Monte Carlo simulation.

23 The uncertainty in E_{R,F-GHG} is obtained by allocating the estimates of uncertainties to the total GHGRP-reported
24 emissions from each of the six industry segments, and then running a Monte Carlo simulation which results in the 95
25 percent CI for emissions from GHGRP reporting facilities (E_{R,F-GHG}).

26 The uncertainty in E_{R,N₂O} is obtained by assuming that the uncertainty in the emissions reported by each of the
27 GHGRP reporting facilities results from the uncertainty in quantity of N₂O consumed and the N₂O emission factor
28 (or utilization). Similar to analyses completed for subpart I (see *Technical Support for Modifications to the*
29 *Fluorinated Greenhouse Gas Emission Estimation Method Option for Semiconductor Facilities* under Subpart I,
30 docket EPA–HQ–OAR–2011–0028), the uncertainty of N₂O consumed was assumed to be 20 percent. Consumption
31 of N₂O for GHGRP reporting facilities was estimated by back- calculating from emissions reported and assuming no
32 abatement. The quantity of N₂O utilized (the complement of the emission factor) was assumed to have a triangular
33 distribution with a minimum value of zero percent, mode of 20 percent and maximum value of 84 percent. The
34 minimum was selected based on physical limitations, the mode was set equivalent to the subpart I default N₂O
35 utilization rate for chemical vapor deposition, and the maximum was set equal to the maximum utilization rate found
36 in ISMI Analysis of Nitrous Oxide Survey Data (ISMI, 2009). The inputs were used to simulate emissions for each
37 of the GHGRP reporting, N₂O-emitting facilities. The uncertainty for the total reported N₂O emissions was then
38 estimated by combining the uncertainties of each of the facilities reported emissions using Monte Carlo simulation.

39 The estimate of uncertainty in E_{NR,F-GHG} and E_{NR,N₂O} entailed developing estimates of uncertainties for the emissions
40 factors for each non-reporting sub-category and the corresponding estimates of TMLA.

41 The uncertainty in TMLA depends on the uncertainty of two variables—an estimate of the uncertainty in the average
42 annual capacity utilization for each level of production of fabs (e.g., full scale or R&D production) and a

⁶⁹ On November 13, 2013, EPA published a final rule revising subpart I (Electronics Manufacturing) of the GHGRP (78 FR 68162). The revised rule includes updated default emission factors and updated default destruction and removal efficiencies that are slightly different from those that semiconductor manufacturers were required to use to report their 2012 emissions. The uncertainty analyses that were performed during the development of the revised rule focused on these updated defaults, but are expected to be reasonably representative of the uncertainties associated with the older defaults, particularly for estimates at the country level. (They may somewhat underestimate the uncertainties associated with the older defaults at the facility level.) For simplicity, the 2012 estimates are assumed to be unbiased although in some cases, the updated (and therefore more representative) defaults are higher or lower than the older defaults. Multiple models and sensitivity scenarios were run for the subpart I analysis. The uncertainty analysis presented here made use of the Input gas and wafer size model (Model 1) under the following conditions: Year = 2010, f = 20, n = SIA3.

1 corresponding estimate of the uncertainty in the number of layers manufactured. For both variables, the distributions
 2 of capacity utilizations and number of manufactured layers are assumed triangular for all categories of non-reporting
 3 fabs. For production fabs and for facilities that manufacture discrete devices, the most probable utilization is
 4 assumed to be 82 percent, with the highest and lowest utilization assumed to be 89 percent, and 70 percent,
 5 respectively. The most probable values for utilization for R&D facilities are assumed to be 20 percent, with the
 6 highest utilization at 30 percent, and the lowest utilization at 10 percent. For the triangular distributions that govern
 7 the number of possible layers manufactured, it is assumed the most probable value is one layer less than reported in
 8 the ITRS; the smallest number varied by technology generation between one and two layers less than given in the
 9 ITRS and largest number of layers corresponded to the figure given in the ITRS.

10 The uncertainty bounds for the average capacity utilization and the number of layers manufactured are used as
 11 inputs in a separate Monte Carlo simulation to estimate the uncertainty around the TMLA of both individual
 12 facilities as well as the total non-reporting TMLA of each sub-population.

13 The uncertainty around the emission factors for each non-reporting category of facilities is dependent on the
 14 uncertainty of the total emissions (MMT CO₂ Eq. units) and the TMLA of each reporting facility in that category.
 15 For each subpopulation of reporting facilities, total emissions were regressed on TMLA (with an intercept forced to
 16 zero) for 10,000 emissions and 10,000 TMLA values in a Monte Carlo simulation, which results in 10,000 total
 17 regression coefficients (emission factors). The 2.5th and the 97.5th percentile of these emission factors are
 18 determined and the bounds are assigned as the percent difference from the estimated emission factor.

19 For simplicity, the results of the Monte Carlo simulations on the bounds of the gas- and wafer size-specific
 20 emissions as well as the TMLA and emission factors are assumed to be normally distributed and the uncertainty
 21 bounds are assigned at 1.96 standard deviations around the estimated mean. The departures from normality were
 22 observed to be small.

23 The final step in estimating the uncertainty in emissions of non-reporting facilities is convolving the distribution of
 24 emission factors with the distribution of TMLA using Monte Carlo simulation.

25 The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-93, which is also obtained
 26 by convolving—using Monte Carlo simulation—the distributions of emissions for each reporting and non-reporting
 27 facility. The emissions estimate for total U.S. F-GHG and N₂O emissions from semiconductor manufacturing were
 28 estimated to be between 4.8 and 5.3 MMT CO₂ Eq. at a 95 percent confidence level. This range represents 5 percent
 29 below to 5 percent above the 2015 emission estimate of 5.0 MMT CO₂ Eq. This range and the associated
 30 percentages apply to the estimate of total emissions rather than those of individual gases. Uncertainties associated
 31 with individual gases will be somewhat higher than the aggregate, but were not explicitly modeled.

32 **Table 4-93: Approach 2 Quantitative Uncertainty Estimates for HFC, PFC, SF₆, NF₃ and N₂O**
 33 **Emissions from Semiconductor Manufacture (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound ^b	Upper Bound ^b	Lower Bound	Upper Bound
Semiconductor Manufacture	HFC, PFC, SF ₆ , NF ₃ , and N ₂ O	5.0	4.8	5.3	-5%	5%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

^b Absolute lower and upper bounds were calculated using the corresponding lower and upper bounds in percentages.

34 The emissions reported under EPA's GHGRP for 2014 and 2015, which are included in the overall emissions
 35 estimated for 2014 and 2015, were based on an updated set of default emission factors. This may have affected the
 36 trend seen between 2013 and 2014 (a 13 percent increase), which reversed the trend seen between 2011 and 2013.
 37 As discussed in the Planned Improvements section, EPA is considering further analysis to determine how much, if
 38 any, of the 2013 to 2014 trend may be attributable to the updated factors.

1 Recalculations Discussion

2 Emissions from 2011 through 2014 were updated to reflect updated emissions reporting in EPA's GHGRP. Further,
3 gas-process specific non-reporter emission factors were updated to reflect the historical changes in GHGRP data as
4 well as updated manufacturing utilizations.

5 Planned Improvements

6 This Inventory contains estimates of seven fluorinated gases for semiconductor manufacturing and N₂O. However,
7 other fluorinated gases (e.g., C₅F₈) are used in relatively smaller amounts. Previously, emissions data for these other
8 fluorinated gases was not reported through the EPA Partnership. Through EPA's GHGRP, these data, as well as heat
9 transfer fluid emission data, are available. Therefore, a point of consideration for future Inventory reports is the
10 inclusion of other fluorinated gases, and emissions from heat transfer fluid (HTF) loss to the atmosphere.

11 Emissions from fluorinated heat transfer fluids, of which some are liquid perfluorinated compounds, are presented in
12 Table 4-91 for informational purposes for 2011 through 2015, and are based upon GHGRP-reported emissions. The
13 GHGRP-reported HTF emissions along with WFF database could be used to develop emission factors for identified
14 subpopulations. Further research needs to be done to determine if the same subpopulations identified in developing
15 new emission factors for F-GHGs are applicable or new subpopulations have to be studied as HTFs are used
16 primarily by manufacturers of wafer size 300 mm and above. Currently, HTF emissions have only been estimated
17 for those years for which there was reported data available. In the future, back casting could be applied to determine
18 HTF emissions for the semiconductor industry prior to 2011.

19 Along with more emissions information for semiconductor manufacturing, EPA's GHGRP requires the reporting of
20 emissions from other types of electronics manufacturing, including micro-electro-mechanical systems (MEMs), flat
21 panel displays, and photovoltaic cells. There currently are five MEMs manufacturers and no flat panel displays and
22 photovoltaic cell manufacturing facilities reporting to EPA's GHGRP. The MEMs manufacturers also report
23 emissions from semiconductor manufacturing and do not distinguish between these two types of manufacturing in
24 their report; thus, emissions from MEMs manufacturers are included in the totals here. Emissions from
25 manufacturing of flat panel displays and photovoltaic cells may be included in future Inventory reports; however,
26 estimation methodologies would need to be developed.

27 The Inventory methodology uses data reported through the EPA Partnership (for earlier years) and EPA's GHGRP
28 (for later years) to extrapolate the emissions of the non-reporting population. While these techniques are well
29 developed, the understanding of the relationship between the reporting and non-reporting populations is limited.
30 Further analysis of the reporting and non-reporting populations could aid in the accuracy of the non-reporting
31 population extrapolation in future years.

32 The Inventory uses utilization from two different sources for various time periods—SEMI to develop PEVM and to
33 estimate non-Partner emissions for the period 1995 to 2010 and U.S. Census Bureau for 2011 through 2014. SEMI
34 reported global capacity utilization for manufacturers through 2011. U.S. Census Bureau capacity utilization include
35 U.S. semiconductor manufacturers as well as assemblers. Further analysis on the impacts of using a new and
36 different source of utilization data could prove to be useful in better understanding of industry trends and impacts of
37 utilization data sources on historical emission estimates.

38 Starting with 2014 reported emissions, EPA's GHGRP required semiconductor manufacturers to apply updated
39 emission factors to estimate their F-GHG emissions. EPA is planning to investigate whether and how much this
40 change may have affected the trend seen in estimated emissions between 2013 and 2014.

4.23 Substitution of Ozone Depleting Substances (IPCC Source Category 2F)

Hydrofluorocarbons (HFCs) and perfluorocarbons (PFCs) are used as alternatives to several classes of ozone-depleting substances (ODSs) that are being phased out under the terms of the Montreal Protocol and the Clean Air Act Amendments of 1990.⁷⁰ Ozone depleting substances—chlorofluorocarbons (CFCs), halons, carbon tetrachloride, methyl chloroform, and hydrochlorofluorocarbons (HCFCs)—are used in a variety of industrial applications including refrigeration and air conditioning equipment, solvent cleaning, foam production, sterilization, fire extinguishing, and aerosols. Although HFCs and PFCs are not harmful to the stratospheric ozone layer, they are potent greenhouse gases. Emission estimates for HFCs and PFCs used as substitutes for ODSs are provided in Table 4-94 and Table 4-95.

Table 4-94: Emissions of HFCs and PFCs from ODS Substitutes (MMT CO₂ Eq.)

Gas	1990	2005	2011	2012	2013	2014	2015
HFC-23	+	+	+	+	+	+	+
HFC-32	+	0.3	3.4	4.4	5.4	6.4	7.5

+ Does not exceed 0.5 MT.

M (Mixture of Gases)

^a Others include HFC-152a, HFC-227ea, HFC-245fa, HFC-43-10mee, HFO-1234yf, C₄F₁₀, and PFC/PFPEs, the latter being a proxy for a diverse collection of PFCs and perfluoropolyethers (PFPEs) employed for solvent applications.

In 1990 and 1991, the only significant emissions of HFCs and PFCs as substitutes to ODSs were relatively small amounts of HFC-152a—used as an aerosol propellant and also a component of the refrigerant blend R-500 used in chillers—and HFC-134a in refrigeration end-uses. Beginning in 1992, HFC-134a was used in growing amounts as a

⁷⁰ [42 U.S.C § 7671, CAA Title VI]

1 refrigerant in motor vehicle air-conditioners and in refrigerant blends such as R-404A.⁷¹ In 1993, the use of HFCs in
 2 foam production began, and in 1994 ODS substitutes for halons entered widespread use in the United States as halon
 3 production was phased-out. In 1995, these compounds also found applications as solvents.

4 The use and subsequent emissions of HFCs and PFCs as ODS substitutes has been increasing from small amounts in
 5 1990 to 168.6 MMT CO₂ Eq. emitted in 2015. This increase was in large part the result of efforts to phase out CFCs
 6 and other ODSs in the United States. In the short term, this trend is expected to continue, and will likely continue
 7 over the next decade as HCFCs, which are interim substitutes in many applications, are themselves phased-out under
 8 the provisions of the Copenhagen Amendments to the Montreal Protocol. Improvements in the technologies
 9 associated with the use of these gases and the introduction of alternative gases and technologies, however, may help
 10 to offset this anticipated increase in emissions.

11 Table 4-96 presents emissions of HFCs and PFCs as ODS substitutes by end-use sector for 1990 through 2015. The
 12 end-use sectors that contributed the most toward emissions of HFCs and PFCs as ODS substitutes in 2015 include
 13 refrigeration and air-conditioning (144.9 MMT CO₂ Eq., or approximately 86 percent), aerosols (11.0 MMT CO₂
 14 Eq., or approximately 7 percent), and foams (9.4 MMT CO₂ Eq., or approximately 6 percent). Within the
 15 refrigeration and air-conditioning end-use sector, motor vehicle air-conditioning was the highest emitting end-use
 16 (38.3 MMT CO₂ Eq.), followed by refrigerated retail food and refrigerated transport. Each of the end-use sectors is
 17 described in more detail below.

18 **Table 4-96: Emissions of HFCs and PFCs from ODS Substitutes (MMT CO₂ Eq.) by Sector**

Sector	1990	2005	2011	2012	2013	2014	2015
Refrigeration/Air Conditioning	+	87.8	125.9	130.0	133.6	139.2	144.9
Aerosols	0.3	7.6	10.1	10.3	10.5	10.8	11.0
Foams	+	2.1	6.4	6.9	7.5	8.0	9.4
Solvents	+	1.7	1.7	1.7	1.8	1.8	1.8
Fire Protection	+	0.7	1.2	1.3	1.3	1.4	1.5
Total	0.3	99.8	145.4	150.2	154.7	161.3	168.6

19 + Does not exceed 0.05 MMT CO₂ Eq.

20 Note: Totals may not sum due to independent rounding.

21 Refrigeration/Air Conditioning

22 The refrigeration and air-conditioning sector includes a wide variety of equipment types that have historically used
 23 CFCs or HCFCs. End-uses within this sector include motor vehicle air-conditioning, retail food refrigeration,
 24 refrigerated transport (e.g., ship holds, truck trailers, railway freight cars), household refrigeration, residential and
 25 small commercial air-conditioning and heat pumps, chillers (large comfort cooling), cold storage facilities, and
 26 industrial process refrigeration (e.g., systems used in food processing, chemical, petrochemical, pharmaceutical, oil
 27 and gas, and metallurgical industries). As the ODS phaseout has taken effect, most equipment has been retrofitted or
 28 replaced to use HFC-based substitutes. Common HFCs in use today in refrigeration/air-conditioning equipment are
 29 HFC-134a, R-410A,⁷² R-404A, and R-507A.⁷³ Lower -GWP options such as HFO-1234yf in motor vehicle air-
 30 conditioning, R-717 (ammonia) in cold storage and industrial applications, and R-744 (carbon dioxide) and
 31 HFC/HFO blends in retail food refrigeration, are also being used. These refrigerants are emitted to the atmosphere
 32 during equipment manufacture and operation (as a result of component failure, leaks, and purges), as well as at
 33 servicing and disposal events.

34 Aerosols

35 Aerosol propellants are used in metered dose inhalers (MDIs) and a variety of personal care products and
 36 technical/specialty products (e.g., duster sprays and safety horns). Many pharmaceutical companies that produce
 37 MDIs—a type of inhaled therapy used to treat asthma and chronic obstructive pulmonary disease—have replaced

⁷¹ R-404A contains HFC-125, HFC-143a, and HFC-134a.

⁷² R-410A contains HFC-32 and HFC-125.

⁷³ R-507A, also called R-507, contains HFC-125 and HFC-143a.

1 the use of CFCs with HFC-propellant alternatives. The earliest ozone-friendly MDIs were produced with HFC-134a,
2 but the industry has started to use HFC-227ea as well. Conversely, since the use of CFC propellants was banned in
3 1978, most non-medical consumer aerosol products have not transitioned to HFCs, but to “not-in-kind”
4 technologies, such as solid roll-on deodorants and finger-pump sprays. The transition away from ODS in specialty
5 aerosol products has also led to the introduction of non-fluorocarbon alternatives (e.g., hydrocarbon propellants) in
6 certain applications, in addition to HFC-134a or HFC-152a. Other low-GWP options such as HFO-1234ze(E) are
7 being used as well. These propellants are released into the atmosphere as the aerosol products are used.

8 **Foams**

9 Chlorofluorocarbons and HCFCs have traditionally been used as foam blowing agents to produce polyurethane
10 (PU), polystyrene, polyolefin, and phenolic foams, which are used in a wide variety of products and applications.
11 Since the Montreal Protocol, flexible PU foams as well as other types of foam, such as polystyrene sheet, polyolefin,
12 and phenolic foam, have transitioned almost completely away from fluorocompounds, into alternatives such as CO₂
13 and hydrocarbons. The majority of rigid PU foams have transitioned to HFCs—primarily HFC-134a and HFC-
14 245fa. Today, these HFCs are used to produce PU appliance, PU commercial refrigeration, PU spray, and PU panel
15 foams—used in refrigerators, vending machines, roofing, wall insulation, garage doors, and cold storage
16 applications. In addition, HFC-152a, HFC-134a and CO₂ are used to produce polystyrene sheet/board foam, which is
17 used in food packaging and building insulation. Low-GWP fluorinated foam blowing agents in use include HFO-
18 1234ze(E) and -1233zd(E). Emissions of blowing agents occur when the foam is manufactured as well as during the
19 foam lifetime and at foam disposal, depending on the particular foam type.

20 **Solvents**

21 Chlorofluorocarbons, methyl chloroform (1,1,1-trichloroethane or TCA), and to a lesser extent carbon tetrachloride
22 (CCl₄) were historically used as solvents in a wide range of cleaning applications, including precision, electronics,
23 and metal cleaning. Since their phaseout, metal cleaning end-use applications have primarily transitioned to non-
24 fluorocarbon solvents and not-in-kind processes. The precision and electronics cleaning end-uses have transitioned
25 in part to high-GWP gases, due to their high reliability, excellent compatibility, good stability, low toxicity, and
26 selective solvency. These applications rely on HFC-43-10mee, HFC-365mfc, HFC-245fa, and to a lesser extent,
27 PFCs. Electronics cleaning involves removing flux residue that remains after a soldering operation for printed circuit
28 boards and other contamination-sensitive electronics applications. Precision cleaning may apply to either electronic
29 components or to metal surfaces, and is characterized by products, such as disk drives, gyroscopes, and optical
30 components, that require a high level of cleanliness and generally have complex shapes, small clearances, and other
31 cleaning challenges. The use of solvents yields fugitive emissions of these HFCs and PFCs.

32 **Fire Protection**

33 Fire protection applications include portable fire extinguishers (“streaming” applications) that originally used halon
34 1211, and total flooding applications that originally used halon 1301, as well as some halon 2402. Since the
35 production and import of virgin halons were banned in the United States in 1994, the halon replacement agent of
36 choice in the streaming sector has been dry chemical, although HFC-236fa is also used to a limited extent. In the
37 total flooding sector, HFC-227ea has emerged as the primary replacement for halon 1301 in applications that require
38 clean agents. Other HFCs, such as HFC-23 and HFC-125, are used in smaller amounts. The majority of HFC-227ea
39 in total flooding systems is used to protect essential electronics, as well as in civil aviation, military mobile weapons
40 systems, oil/gas/other process industries, and merchant shipping. Fluoroketone FK-5-1-12 is also used as a low-
41 GWP option and 2-BTP is being considered. As fire protection equipment is tested or deployed, emissions of these
42 HFCs occur.

43 **Methodology**

44 A detailed Vintaging Model of ODS-containing equipment and products was used to estimate the actual—versus
45 potential—emissions of various ODS substitutes, including HFCs and PFCs. The name of the model refers to the
46 fact that it tracks the use and emissions of various compounds for the annual “vintages” of new equipment that enter
47 service in each end-use. The Vintaging Model predicts ODS and ODS substitute use in the United States based on

modeled estimates of the quantity of equipment or products sold each year containing these chemicals and the amount of the chemical required to manufacture and/or maintain equipment and products over time. Emissions for each end-use were estimated by applying annual leak rates and release profiles, which account for the lag in emissions from equipment as they leak over time. By aggregating the data for 65 different end-uses, the model produces estimates of annual use and emissions of each compound. Further information on the Vintaging Model is contained in Annex 3.9.

Uncertainty and Time-Series Consistency – TO BE UPDATED FOR FINAL INVENTORY REPORT

Given that emissions of ODS substitutes occur from thousands of different kinds of equipment and from millions of point and mobile sources throughout the United States, emission estimates must be made using analytical tools such as the Vintaging Model or the methods outlined in IPCC (2006). Though the model is more comprehensive than the IPCC default methodology, significant uncertainties still exist with regard to the levels of equipment sales, equipment characteristics, and end-use emissions profiles that were used to estimate annual emissions for the various compounds.

The Vintaging Model estimates emissions from 65 end-uses. The uncertainty analysis, however, quantifies the level of uncertainty associated with the aggregate emissions resulting from the top 21 end-uses, comprising over 95 percent of the total emissions, and 6 other end-uses. These 27 end-uses comprise 97 percent of the total emissions, equivalent to 156.4 MMT CO₂ Eq. In an effort to improve the uncertainty analysis, additional end-uses are added annually, with the intention that over time uncertainty for all emissions from the Vintaging Model will be fully characterized. Any end-uses included in previous years' uncertainty analysis were included in the current uncertainty analysis, whether or not those end-uses were included in the top 95 percent of emissions from ODS substitutes.

In order to calculate uncertainty, functional forms were developed to simplify some of the complex “vintaging” aspects of some end-use sectors, especially with respect to refrigeration and air-conditioning, and to a lesser degree, fire extinguishing. These sectors calculate emissions based on the entire lifetime of equipment, not just equipment put into commission in the current year, thereby necessitating simplifying equations. The functional forms used variables that included growth rates, emission factors, transition from ODSs, change in charge size as a result of the transition, disposal quantities, disposal emission rates, and either stock for the current year or original ODS consumption. Uncertainty was estimated around each variable within the functional forms based on expert judgment, and a Monte Carlo analysis was performed. The most significant sources of uncertainty for this source category include the emission factors for residential unitary air-conditioners, as well as the percent of non-MDI aerosol propellant that is HFC-152a.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-97. Substitution of ozone depleting substances HFC and PFC emissions were estimated to be between 154.2 and 172.5 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 1.4 percent below to 10.3 percent above the emission estimate of 156.4 MMT CO₂ Eq., which comprises 97 percent of total emissions.

Table 4-97: Approach 2 Quantitative Uncertainty Estimates for HFC and PFC Emissions from ODS Substitutes (MMT CO₂ Eq. and Percent)

Source	Gases	2015 Emission Estimate (MMT CO ₂ Eq.) ^a	Uncertainty Range Relative to Emission Estimate ^b (%)			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Substitution of Ozone Depleting Substances	HFCs and PFCs	156.4	154.2	172.5	-1.4%	+10.3%

^a 2015 emission estimates and the uncertainty range presented in this table correspond to selected end-uses within the aerosols, foams, solvents, fire extinguishing agents, and refrigerants sectors that comprise 97 percent of total emissions, but not for other remaining categories. Therefore, because the uncertainty associated with emissions from “other” ODS substitutes was not estimated, they were excluded in the uncertainty estimates reported in this table.

^b Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

1
2 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
3 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
4 above.

5 **Comparison of Reported Consumption to Modeled Consumption of HFCs**

6 Data from EPA's Greenhouse Gas Reporting Program (GHGRP) was also used to perform quality control on the
7 modeled emissions from this source category. To do so, consumption patterns demonstrated through data reported
8 under GHGRP Subpart OO: Suppliers of Industrial Greenhouse Gases and Subpart QQ: Imports and Exports of
9 Equipment Pre-charged with Fluorinated GHGs or Containing Fluorinated GHGs in Closed-cell Foams were
10 compared to the modeled demand for new saturated HFCs (excluding HFC-23) used as ODS substitutes from the
11 Vintaging Model. The collection of data from suppliers of HFCs enables EPA to calculate the reporters' aggregated
12 net supply—the sum of the quantities of chemical produced or imported into the United States less the sum of the
13 quantities of chemical transformed (used as a feedstock in the production of other chemicals), destroyed, or exported
14 from the United States.⁷⁴ This allows for a quality control check on emissions from this source because the
15 Vintaging Model uses modeled demand for new chemical as a proxy for total amount supplied, which is similar to
16 net supply, as an input to the emission calculations in the model.

17 *Reported Net Supply (GHGRP Top-Down Estimate)*

18 Under EPA's GHGRP, suppliers (i.e., producers, importers, and exporters) of HFCs under Subpart OO began
19 annually reporting their production, transformation, destruction, imports, and exports to EPA in 2011 (for supply
20 that occurred in 2010) and suppliers of HFCs under Subpart QQ began annually reporting their imports and exports
21 to EPA in 2012 (for supply that occurred in 2011). Beginning in 2015, bulk consumption data for aggregated HFCs
22 reported under Subpart OO were made publicly available under EPA's GHGRP. Data include all saturated HFCs
23 (except HFC-23) reported to EPA across the GHGRP-reporting time series (2010 through 2015). The data include
24 all 26 such saturated HFCs listed in Table A-1 of 40 CFR Part 98, where regulations for EPA's GHGRP are
25 promulgated, though not all species were reported in each reporting year. For the first time in 2016, net imports of
26 HFCs contained in pre-charged equipment or closed-cell foams reported under Subpart QQ were made publicly
27 available under EPA's GHGRP across the GHGRP-reporting time series (2010 through 2015).

28 *Modeled Consumption (Vintaging Model Bottom-Up Estimate)*

29 The Vintaging Model, used to estimate emissions from this source category, calculates chemical demand based on
30 the quantity of equipment and products sold, serviced and retired each year, and the amount of the chemical required
31 to manufacture and/or maintain the equipment and products.⁷⁵ It is assumed that the total demand equals the amount
32 supplied by either new production, chemical import, or quantities recovered (usually reclaimed) and placed back on
33 the market. In the Vintaging Model, demand for new chemical, as a proxy for consumption, is calculated as any
34 chemical demand (either for new equipment or for servicing existing equipment) that cannot be met through
35 recycled or recovered material. No distinction is made in the Vintaging Model between whether that need is met
36 through domestic production or imports. To calculate emissions, the Vintaging Model estimates the quantity
37 released from equipment over time. Thus, verifying the Vintaging Model's calculated consumption against GHGRP
38 reported data is one way to check the Vintaging Model's emission estimates.

39 There are ten saturated HFC species modeled in the Vintaging Model: HFC-23, HFC-32, HFC-125, HFC-134a,
40 HFC-143a, HFC-152a, HFC-227ea, HFC-236fa, HFC-245fa, and HFC-43-10mee. For the purposes of this
41 comparison, only nine HFC species are included (HFC-23 is excluded), to more closely align with the aggregated
42 total reported under EPA's GHGRP. While some amounts of less-used saturated HFCs, including isomers of those

⁷⁴ Chemical that is exported, transformed, or destroyed—unless otherwise imported back to the United States—will never be emitted in the United States.

⁷⁵ The model builds an inventory of the in-use stock of equipment and products and ODSs and HFCs in each of the sub-applications. Emissions are subsequently estimated by applying annual and disposal emission rates to each population of equipment and products.

1 included in the Vintaging Model, are reportable under EPA’s GHGRP, the data are believed to represent an amount
 2 comparable to the modeled estimates as a quality control check.

3 *Comparison Results and Discussion*

4 Comparing the estimates of consumption from these two approaches (i.e., reported and modeled) ultimately supports
 5 and improves estimates of emissions, as noted in the 2006 IPCC Guidelines for National Greenhouse Gas
 6 Inventories (which refer to fluorinated greenhouse gas consumption based on supplies as “potential emissions”):

7 [W]hen considered along with estimates of actual emissions, the potential emissions approach can assist in
 8 validation of completeness of sources covered and as a QC check by comparing total domestic
 9 consumption as calculated in this ‘potential emissions approach’ per compound with the sum of all activity
 10 data of the various uses (IPCC 2006).

11 Table 4-98 and Figure 4-2 compare the net supply of saturated HFCs (excluding HFC-23) in MMT CO₂ Eq. as
 12 determined from Subpart OO (industrial GHG suppliers) and Subpart QQ (supply of HFCs in products) of EPA’s
 13 GHGRP for the years 2010 through 2015 and the chemical demand as calculated by the Vintaging Model for the
 14 same time series.

15 **Table 4-98: U.S. HFC Consumption (MMT CO₂ Eq.)**

	2010	2011	2012	2013	2014	2015
Reported Net Supply (GHGRP)	235	249	245	295	279	290
Industrial GHG Suppliers	235	241	227	278	254	264
Imports of HFCs in Products	N/A ^a	7	18	17	25	26
Modeled Supply (Vintaging Model)	256	256	273	278	282	285
Percent Difference	9%	3%	11%	-6%	1%	-2%

16 ^a Importers and exporters of fluorinated gases in products were not required to report until 2011.
 17

18 **Figure 4-2: U.S. HFC Consumption (MMT CO₂ Eq.)**

19 As shown, the estimates from the Vintaging Model are generally higher than the GHGRP estimates by an average of
 20 3 percent across the time series (i.e., 2010 through 2015). Potential reasons for these differences include:
 21

- 22 • The Vintaging Model includes fewer HFCs than are reported to EPA’s GHGRP. However, the additional
 23 reported HFCs represent a small fraction of total HFC use for this source category, both in GWP-weighted
 24 and unweighted terms, and as such, it is not expected that the additional HFCs reported to EPA are a major
 25 driver for the difference between the two sets of estimates. To the extent lower-GWP isomers were used in

lieu of the modeled chemicals (e.g., HFC-134 instead of HFC-134a), lower CO₂ Eq. amounts in the EPA's GHGRP data compared to the modeled estimates would be expected.

- Because the top-down data are reported at the time of actual production or import and the bottom-up data are calculated at the time of actual placement on the market, there could be a temporal discrepancy when comparing data. Because the EPA's GHGRP data generally increases over time (although some year-to-year variations exist) and the Vintaging Model estimates also increase, EPA would expect the modeled estimates to be slightly lower than the corresponding GHGRP data due to this temporal effect.
- Under EPA's GHGRP, all facilities that produce HFCs are required to report their quantities, whereas importers or exporters of HFCs or pre-charged equipment and closed-cell foams that contain HFCs are only required to report if either their total imports or their total exports of greenhouse gases are greater than or equal to 25,000 metric tons of CO₂ Eq. per year. Thus, some imports may not be accounted for in the GHGRP data. On the other hand, some exports might also not be accounted for in this data.
- In some years, imports and exports may be greater than consumption because the excess is being used to increase chemical or equipment stockpiles; in other years, the opposite may hold true. Similarly, relocation of manufacturing facilities or recovery from the recession could contribute to variability in imports or exports. Averaging imports and exports over multiple years can minimize the impact of such fluctuations. For example, when the 2012 and 2013 net additions to the supply are averaged, as shown in Table 4-99, the percent difference between the consumption estimates decreases compared to the 2012-only estimates.

Table 4-99: Averaged U.S. HFC Demand (MMT CO₂ Eq.)

	2010-2011 Avg.	2011-2012 Avg.	2012-2013 Avg.	2013-2014 Avg.	2014-2015 Avg.
Reported Net Supply (GHGRP)	242	247	270	287	284
Modeled Demand (Vintaging Model)	256	264	275	280	284
Percent Difference	6%	7%	2%	-2%	0%

- The Vintaging Model does not reflect the dynamic nature of reported HFC consumption, with significant differences seen in each year. Whereas the Vintaging Model projects a slowly increasing overall demand, actual consumption for specific chemicals or equipment may vary over time and could even switch from positive to negative (indicating more chemical exported, transformed, or destroyed than produced or imported in a given year). Furthermore, consumption as calculated in the Vintaging Model is a function of demand not met by disposal recovery. If, in any given year, a significant number of units are disposed, there will be a large amount of additional recovery in that year that can cause an unexpected and not modeled decrease in demand and thus a decrease in consumption. On the other hand, if market, economic, or other factors cause less than expected disposal and recovery, actual supply would decrease, and hence consumption would increase to meet that demand not satisfied by recovered quantities, increasing the GHGRP data and bringing those totals closer to the Vintaging Model estimates.
- The Vintaging Model is used to estimate the emissions that occur in the United States. As such, all equipment or products that contain ODS or alternatives, including saturated HFCs, are assumed to consume and emit chemicals equally as like equipment or products originally produced in the United States. The GHGRP data from Subpart OO (industrial GHG suppliers) includes HFCs produced or imported and used to fill or manufacture products that are then exported from the United States. The Vintaging Model estimates of demand and supply are not meant to incorporate such chemical. Likewise, chemicals may be used outside the United States to create products or charge equipment that is then imported to and used in the United States. The Vintaging Model estimates of demand and supply are meant to capture this chemical, as it will lead to emissions inside the United States. The GHGRP data from Subpart QQ (supply of HFCs in products) accounts for some of these differences; however, the scope of Subpart QQ does not cover all such equipment or products and the chemical contained therein. Depending on whether the United States is a net importer or net exporter of such chemical, this factor may account for some of the difference shown above or might lead to a further discrepancy.

One factor, however, would only lead to modeled estimates to be even higher than the estimates shown and hence for most years higher than EPA's GHGRP data:

- Saturated HFCs are also known to be used as a cover gas in the production of magnesium. The Vintaging Model estimates here do not include the amount of HFCs for this use, but rather only the amount for uses

1 that traditionally were served by ODS. Nonetheless, EPA expects that this supply not included in the
2 Vintaging Model estimates to be very small compared to the ODS substitute use for the years analyzed. An
3 indication of the different magnitudes of these categories is seen in the fact that the 2015 emissions from
4 that non-modeled source (0.1 MMT CO₂ Eq.) are much smaller than those for the ODS substitute sector
5 (168.6 MMT CO₂ Eq).
6

7 Using a Tier 2 bottom-up modeling methodology to estimate emissions requires assumptions and expert judgement.
8 Comparing the Vintaging Model's estimates to GHGRP reported estimates, particularly for more widely used
9 chemicals, can help validate the model but it is expected that the model will have limitations. This comparison
10 shows that Vintaging Model consumption estimates are well within the same order of magnitude as the actual
11 consumption data as reported to EPA's GHGRP although the differences in reported net supply and modeled
12 demand are still significant in some of the years. Although it can be difficult to capture the observed market
13 variability, the Vintaging Model is periodically reviewed and updated to ensure that the model reflects the current
14 and future trajectory of ODS and ODS substitutes across all end-uses and the Vintaging Model will continue to be
15 compared to available top-down estimates in order to ensure the model accurately estimates HFC consumption and
16 emissions.

17 Recalculations Discussion

18 For the current Inventory, reviews of the foams sector resulted in revisions to the Vintaging Model since the
19 previous Inventory report. Methodological recalculations were applied to the entire time-series to ensure time-series
20 consistency from 1990 through 2015. For the foams sector, assumptions regarding lifetimes and loss rates were
21 revised based on a review of *2006 IPCC Guidelines for National Greenhouse Gas Inventories*. Combined, these
22 assumption changes decreased CO₂-equivalent greenhouse gas emissions on average by 0.2 percent between 1990
23 and 2015.

24 Planned Improvements

25 Future improvements to the Vintaging Model are planned for the refrigeration and air-conditioning, foam, and
26 aerosols sectors. A refrigerated food processing and dispensing equipment end-use may be added to the refrigeration
27 and air-conditioning sector, in order to capture a portion of the retail food market that may not be adequately
28 encompassed by the small retail food end-use. In addition, end-uses representing medium-duty and heavy-duty
29 vehicle and truck air conditioners may be added to the refrigeration and air-conditioning sector.

30 New vintages will be added for the motor vehicle air-conditioning, large retail food, medium retail food, small retail
31 food, vending machines, cold storage, household refrigerators and freezers, aerosols, and multiple foam end-uses.
32 These vintages will include transitions to low-GWP alternatives as companies begin to comply with rules issued
33 under EPA's Significant New Alternatives Policy (SNAP) Program. These updates to the Vintaging Model are
34 anticipated to have the greatest impact on the estimates of greenhouse gas emissions for the refrigeration and air-
35 conditioning and foams sectors in the near term, and are also anticipated to have an increasingly larger impact in
36 future years as the low-GWP alternatives penetrate the U.S. market.

37 4.24 Electrical Transmission and Distribution 38 (IPCC Source Category 2G1)

39 The largest use of sulfur hexafluoride (SF₆), both in the United States and internationally, is as an electrical insulator
40 and interrupter in equipment that transmits and distributes electricity (RAND 2004). The gas has been employed by
41 the electric power industry in the United States since the 1950s because of its dielectric strength and arc-quenching
42 characteristics. It is used in gas-insulated substations, circuit breakers, and other switchgear. SF₆ has replaced
43 flammable insulating oils in many applications and allows for more compact substations in dense urban areas.

1 Fugitive emissions of SF₆ can escape from gas-insulated substations and switchgear through seals, especially from
 2 older equipment. The gas can also be released during equipment manufacturing, installation, servicing, and disposal.
 3 Emissions of SF₆ from equipment manufacturing and from electrical transmission and distribution systems were
 4 estimated to be 4.2 MMT CO₂ Eq. (0.2 kt) in 2015. This quantity represents an 82 percent decrease from the
 5 estimate for 1990 (see Table 4-100 and Table 4-101). There are two potential causes for this decrease: a sharp
 6 increase in the price of SF₆ during the 1990s and a growing awareness of the magnitude and environmental impact
 7 of SF₆ emissions through programs such as EPA’s voluntary SF₆ Emission Reduction Partnership for Electric Power
 8 Systems (Partnership) and EPA’s GHGRP. Utilities participating in the Partnership have lowered their emission
 9 factor (kg SF₆ emitted per kg of nameplate capacity) by more than 85 percent since the Partnership began in 1999. A
 10 recent examination of the SF₆ emissions reported by electric power systems to EPA’s GHGRP revealed that SF₆
 11 emissions from reporters have decreased by 28 percent from 2011 to 2015,⁷⁶ with much of the reduction seen from
 12 utilities that are not participants in the Partnership. These utilities may be making relatively large reductions in
 13 emissions as they take advantage of relatively large and/or inexpensive emission reduction opportunities (i.e., “low
 14 hanging fruit,” such as replacing major leaking circuit breakers) that Partners have already taken advantage of under
 15 the voluntary program (Ottinger et al. 2014).

16 **Table 4-100: SF₆ Emissions from Electric Power Systems and Electrical Equipment**
 17 **Manufacturers (MMT CO₂ Eq.)**

Year	Electric Power Systems	Electrical Equipment Manufacturers	Total
1990	22.8	0.3	23.1
2005	7.7	0.5	8.3
2011	5.3	0.7	6.0
2012	4.5	0.3	4.8
2013	4.2	0.4	4.6
2014	4.5	0.4	4.8
2015	3.9	0.3	4.2

Note: Totals may not sum due to independent rounding.

18 **Table 4-101: SF₆ Emissions from Electric Power Systems and Electrical Equipment**
 19 **Manufacturers (kt)**

Year	Emissions
1990	1.0
2005	0.4
2011	0.3
2012	0.2
2013	0.2
2014	0.2
2015	0.2

20 Methodology

21 The estimates of emissions from Electrical Transmission and Distribution are comprised of emissions from electric
 22 power systems and emissions from the manufacture of electrical equipment. The methodologies for estimating both
 23 sets of emissions are described below.

⁷⁶ Analysis of emission trends from the GHGRP is imperfect due to an inconsistent group of reporters year to year.

1990 through 1998 Emissions from Electric Power Systems

Emissions from electric power systems from 1990 through 1998 were estimated based on (1) the emissions estimated for this source category in 1999, which, as discussed in the next section, were based on the emissions reported during the first year of EPA's SF₆ Emission Reduction Partnership for Electric Power Systems (Partnership), and (2) the RAND survey of global SF₆ emissions. Because most utilities participating in the Partnership reported emissions only for 1999 through 2011, modeling was used to estimate SF₆ emissions from electric power systems for the years 1990 through 1998. To perform this modeling, U.S. emissions were assumed to follow the same trajectory as global emissions from this source during the 1990 to 1999 period. To estimate global emissions, the RAND survey of global SF₆ sales were used, together with the following equation for estimating emissions, which is derived from the mass-balance equation for chemical emissions (Volume 3, Equation 7.3) in the *2006 IPCC Guidelines*.⁷⁷ (Although Equation 7.3 of the *2006 IPCC Guidelines* appears in the discussion of substitutes for ozone-depleting substances, it is applicable to emissions from any long-lived pressurized equipment that is periodically serviced during its lifetime.)

$$\text{Emissions (kilograms SF}_6\text{)} = \text{SF}_6 \text{ purchased to refill existing equipment (kilograms)} + \text{nameplate capacity of retiring equipment (kilograms)}^{78}$$

Note that the above equation holds whether the gas from retiring equipment is released or recaptured; if the gas is recaptured, it is used to refill existing equipment, thereby lowering the amount of SF₆ purchased by utilities for this purpose.

Gas purchases by utilities and equipment manufacturers from 1961 through 2003 are available from the RAND (2004) survey. To estimate the quantity of SF₆ released or recovered from retiring equipment, the nameplate capacity of retiring equipment in a given year was assumed to equal 81.2 percent of the amount of gas purchased by electrical equipment manufacturers 40 years previous (e.g., in 2000, the nameplate capacity of retiring equipment was assumed to equal 81.2 percent of the gas purchased in 1960). The remaining 18.8 percent was assumed to have been emitted at the time of manufacture. The 18.8 percent emission factor is an average of IPCC default SF₆ emission rates for Europe and Japan for 1995 (IPCC 2006). The 40-year lifetime for electrical equipment is also based on IPCC (2006). The results of the two components of the above equation were then summed to yield estimates of global SF₆ emissions from 1990 through 1999.

U.S. emissions between 1990 and 1999 are assumed to follow the same trajectory as global emissions during this period. To estimate U.S. emissions, global emissions for each year from 1990 through 1998 were divided by the estimated global emissions from 1999. The result was a time series of factors that express each year's global emissions as a multiple of 1999 global emissions. Historical U.S. emissions were estimated by multiplying the factor for each respective year by the estimated U.S. emissions of SF₆ from electric power systems in 1999 (estimated to be 14.3 MMT CO₂ Eq.).

Two factors may affect the relationship between the RAND sales trends and actual global emission trends. One is utilities' inventories of SF₆ in storage containers. When SF₆ prices rise, utilities are likely to deplete internal inventories before purchasing new SF₆ at the higher price, in which case SF₆ sales will fall more quickly than emissions. On the other hand, when SF₆ prices fall, utilities are likely to purchase more SF₆ to rebuild inventories, in which case sales will rise more quickly than emissions. This effect was accounted for by applying 3-year smoothing to utility SF₆ sales data. The other factor that may affect the relationship between the RAND sales trends and actual global emissions is the level of imports from and exports to Russia and China. SF₆ production in these countries is not included in the RAND survey and is not accounted for in any another manner by RAND. However, atmospheric studies confirm that the downward trend in estimated global emissions between 1995 and 1998 was real (see the Uncertainty discussion below).

⁷⁷ Ideally, sales to utilities in the U.S. between 1990 and 1999 would be used as a model. However, this information was not available. There were only two U.S. manufacturers of SF₆ during this time period, so it would not have been possible to conceal sensitive sales information by aggregation.

⁷⁸ Nameplate capacity is defined as the amount of SF₆ within fully charged electrical equipment.

1999 through 2015 Emissions from Electric Power Systems

Emissions from electric power systems from 1999 to 2015 were estimated based on: (1) reporting from utilities participating in EPA's SF₆ Emission Reduction Partnership for Electric Power Systems (Partners), which began in 1999; (2) reporting from utilities covered by the EPA's GHGRP, which began in 2012 for emissions occurring in 2011 (GHGRP-Only Reporters); and (3) the relationship between utilities' reported emissions and their transmission miles as reported in the 2001, 2004, 2007, 2010, and 2013 Utility Data Institute (UDI) Directories of Electric Power Producers and Distributors (UDI 2001, 2004, 2007, 2010, 2013), which was applied to the electric power systems that do not report to EPA (Non-Reporters). (Transmission miles are defined as the miles of lines carrying voltages above 34.5 kV).

Partners

Over the period from 1999 to 2015, Partner utilities, which for inventory purposes are defined as utilities that either currently are or previously have been part of the Partnership,⁷⁹ represented 48 percent, on average, of total U.S. transmission miles. Partner utilities estimated their emissions using a Tier 3 utility-level mass balance approach (IPCC 2006). If a Partner utility did not provide data for a particular year, emissions were interpolated between years for which data were available or extrapolated based on Partner-specific transmission mile growth rates. In 2012, many Partners began reporting their emissions (for 2011 and later years) through EPA's GHGRP (discussed further below) rather than through the Partnership. In 2015, approximately 0.6 percent of the total emissions attributed to Partner utilities were reported through Partnership reports. Approximately 95 percent of the total emissions attributed to Partner utilities were reported and verified through EPA's GHGRP. Partners without verified 2015 data accounted for approximately 5 percent of the total emissions attributed to Partner utilities.⁸⁰

GHGRP-Only Reporters

EPA's GHGRP requires users of SF₆ in electric power systems to report emissions if the facility has a total SF₆ nameplate capacity that exceeds 17,820 pounds. (This quantity is the nameplate capacity that would result in annual SF₆ emissions equal to 25,000 metric tons of CO₂ equivalent at the historical emission rate reported under the Partnership.) As under the Partnership, electric power systems that report their SF₆ emissions under EPA's GHGRP are required to use the Tier 3 utility-level mass-balance approach. Many Partners began reporting their emissions through EPA's GHGRP in 2012 (reporting emissions for 2011 and later years) because their nameplate capacity exceeded the reporting threshold. Partners who did not report through EPA's GHGRP continued to report through the Partnership.

In addition, many non-Partners began reporting to EPA for the first time through its GHGRP in 2012. Non-Partner emissions reported and verified under EPA's GHGRP were compiled to form a new category of reported data (GHGRP-Only Reporters). GHGRP-Only Reporters accounted for 20 percent of U.S. transmission miles and 24 percent of estimated U.S. emissions from electric power system in 2015.⁸¹

⁷⁹ For the 2015 inventory, partners who had reported three years or less of data prior to 2006 were removed. Most of these partners had been removed from the list of current Partners, but remained in the inventory due to the extrapolation methodology for non-reporting partners.

⁸⁰ It should be noted that data reported through EPA's GHGRP must go through a verification process; only data verified as of September 1, 2016 could be used in the emission estimates for 2015. For Partners whose GHGRP data was not yet verified, emissions were extrapolated based upon historical Partner-specific transmission mile growth rates, and those Partners are included in the 'non-reporting Partners' category.

For electric power systems, verification involved a series of electronic range, completeness, and algorithm checks for each report submitted. In addition, EPA manually reviewed the reported data and compared each facility's reported transmission miles with the corresponding quantity in the UDI 2013 database (UDI 2013). In the first year of GHGRP reporting, EPA followed up with reporters where the discrepancy between the reported miles and the miles published by UDI was greater than 10 percent, with a goal to improve data quality. Only GHGRP data verified as of September 1, 2016 was included in the emission estimates for 2011, 2012, 2013, 2014 and 2015.

⁸¹ GHGRP-reported and Partner transmission miles from a number of facilities were equal to zero with non-zero emissions. These facilities emissions were added to the emissions totals for their respective parent companies when identifiable and not

1 **Non-Reporters**

2 Emissions from Non-Reporters (i.e., utilities other than Partners and GHGRP-Only Reporters) in every year since
 3 1999 were estimated using the results of a regression analysis that correlated emissions from reporting utilities
 4 (using verified data from both Partners and GHGRP-Only Reporters) with their transmission miles.⁸² As noted
 5 above, non-Partner emissions were reported to the EPA for the first time through its GHGRP in 2012 (representing
 6 2011 emissions). This set of reported data was of particular interest because it provided insight into the emission rate
 7 of non-Partners, which previously was assumed to be equal to the historical (1999) emission rate of Partners.
 8 Specifically, emissions were estimated for Non-Reporters as follows:

- 9 • Non-Reporters, 1999 to 2011: First, the 2011 emission rates (per kg nameplate capacity and per
 10 transmission mile) reported by Partners and GHGRP-Only Reporters were reviewed to determine whether
 11 there was a statistically significant difference between these two groups. Transmission mileage data for
 12 2011 was reported through GHGRP, with the exception of transmission mileage data for Partners that did
 13 not report through GHGRP, which was obtained from UDI. It was determined that there is no statistically
 14 significant difference between the emission rates of Partners and GHGRP-Only reporters; therefore, Partner
 15 and GHGRP-Only reported data for 2011 were combined to develop regression equations to estimate the
 16 emissions of Non-Reporters. Historical emissions from Non-Reporters were estimated by linearly
 17 interpolating between the 1999 regression coefficients (based on 1999 Partner data) and the 2011
 18 regression coefficients.
- 19 • Non-Reporters, 2012 to Present: It was determined that there continued to be no statistically significant
 20 difference between the emission rates reported by Partners and by GHGRP-Only Reporters. Therefore, the
 21 emissions data from both groups were combined to develop regression equations for 2012. This was
 22 repeated for 2013, 2014, and 2015 using Partner and GHGRP-Only Reporter data for each year.
- 23 ○ The 2015 regression equation for utilities was developed based on the emissions reported by a subset
 24 of Partner utilities and GHGRP-Only utilities (representing approximately 66 percent of total U.S.
 25 transmission miles). The regression equation for 2015 is:

$$26 \text{ Emissions (kg)} = 0.166 \times \text{Transmission Miles}$$

27
 28 Table 4-102 below shows the percentage of transmission miles covered by reporters (i.e., associated with reported
 29 data) and the regression coefficient for 1999 (the first year data was reported), and for 2011 through 2015 (the first
 30 three years with GHGRP reported data). The coefficient decreased between 2014 and 2015.
 31

32 **Table 4-102: Transmission Mile Coverage and Regression Coefficients (Percent)**

	1999	2011	2012	2013	2014	2015
Percentage of Miles Covered by Reporters	50	68	68	68	68	66
Regression Coefficient ^a	0.71	0.26	0.23	0.22	0.22	0.17

33 ^a Regression coefficient is defined as emissions (in kg) divided by transmission miles.

34
 35 Data on transmission miles for each Non-Reporter for the years 2000, 2003, 2006, and 2009, and 2012 were
 36 obtained from the 2001, 2004, 2007, 2010, and 2013 UDI Directories of Electric Power Producers and Distributors,
 37 respectively (UDI 2001, 2004, 2007, 2010, 2013). The U.S. transmission system grew by over 25,000 miles between
 38 2000 and 2003 yet declined by almost 4,000 miles between 2003 and 2006. Given these fluctuations, periodic
 39 increases are assumed to occur gradually. Therefore, transmission mileage was assumed to increase at an annual rate
 40 of 1.2 percent between 2000 and 2003 and decrease by -0.20 percent between 2003 and 2006. This growth rate grew
 41 to 3 percent from 2006 to 2009 as transmission miles increased by more than 59,000 miles. The annual growth rate

included in the regression equation when not identifiable or applicable. Other facilities reported non-zero transmission miles with zero emissions, or zero transmission miles and zero emissions. These facilities were not included in the development of the regression equations (discussed further below). These emissions are already implicitly accounted for in the relationship between transmission miles and emissions.

⁸² In the United States, SF₆ is contained primarily in transmission equipment rated above 34.5 kV.

1 for 2009 through 2012 was calculated to be 2.0 percent as transmission miles grew by approximately 43,000 during
2 this time period.

3 **Total Industry Emissions**

4 As a final step, total electric power system emissions from 1999 through 2015 were determined for each year by
5 summing the Partner reported and estimated emissions (reported data was available through the EPA’s SF₆ Emission
6 Reduction Partnership for Electric Power Systems), the GHGRP-Only reported emissions, and the non-reporting
7 utilities’ emissions (determined using the regression equations).

8 **1990 through 2015 Emissions from Manufacture of Electrical Equipment**

9 The 1990 to 2015 emission estimates for original equipment manufacturers (OEMs) were derived by assuming that
10 manufacturing emissions equal some percent of the quantity of SF₆ provided with new equipment(described below).
11 The 2011 to 2015 emission estimates for OEMs were obtained from GHGRP Subpart SS emissions, as well as
12 assumptions on the percent share of emissions from GHGRP reporters. The quantity of SF₆ provided with new
13 equipment was estimated based on statistics compiled by the National Electrical Manufacturers Association
14 (NEMA). These statistics were provided for 1990 to 2000; the quantities of SF₆ provided with new equipment for
15 2001 to 2015 were estimated using Partner reported data and the total industry SF₆ nameplate capacity estimate
16 (194.6 MMT CO₂ Eq. in 2015). Specifically, the ratio of new nameplate capacity to total nameplate capacity of a
17 subset of Partners for which new nameplate capacity data was available from 1999 to 2015 was calculated. These
18 ratios were then multiplied by the total industry nameplate capacity estimate for each year to derive the amount of
19 SF₆ provided with new equipment for the entire industry. Emission rates for the time period 1990 to 2000 was
20 assumed to be 10 percent of the quantity of SF₆ provided with new equipment. The 10 percent emission rate is the
21 average of the “ideal” and “realistic” manufacturing emission rates (4 percent and 17 percent, respectively)
22 identified in a paper prepared under the auspices of the International Council on Large Electric Systems (CIGRE) in
23 February 2002 (O’Connell et al. 2002). For the time period 2001 to 2010, the emission rates were estimated by
24 interpolating the emissions rates between 2000 and 2011. The emission rate for 2011 was estimated using the SF₆
25 emissions from Subpart SS reporters, and an assumption that these reported emissions account for a conservative
26 estimate of 50 percent of the total emissions from OEMs. The emissions were divided by the total quantity of SF₆
27 provided with new equipment in 2011 to get an emission rate. Emissions from 2011 to 2015 are obtained from
28 GHGRP Subpart SS emissions and scaled up to assume that GHGRP Subpart SS reporters constitute only 50 percent
29 of the emissions.

30 **Uncertainty and Time-Series Consistency – TO BE UPDATED** 31 **FOR FINAL INVENTORY REPORT**

32 To estimate the uncertainty associated with emissions of SF₆ from Electrical Transmission and Distribution,
33 uncertainties associated with four quantities were estimated: (1) emissions from Partners, (2) emissions from
34 GHGRP-Only Reporters, (3) emissions from Non-Reporters, and (4) emissions from manufacturers of electrical
35 equipment. A Monte Carlo analysis was then applied to estimate the overall uncertainty of the emissions estimate.

36 Total emissions from the SF₆ Emission Reduction Partnership include emissions from both reporting (through the
37 Partnership or GHGRP) and non-reporting Partners. For reporting Partners, individual Partner-reported SF₆ data was
38 assumed to have an uncertainty of 10 percent. Based on a Monte Carlo analysis, the cumulative uncertainty of all
39 Partner-reported data was estimated to be 4.7 percent. The uncertainty associated with extrapolated or interpolated
40 emissions from non-reporting Partners was assumed to be 20 percent.

41 For GHGRP-Only Reporters, reported SF₆ data was assumed to have an uncertainty of 20 percent.⁸³ Based on a
42 Monte Carlo analysis, the cumulative uncertainty of all GHGRP-Only reported data was estimated to be 6.1 percent.

43 There are two sources of uncertainty associated with the regression equations used to estimate emissions in 2013
44 from Non-Reporters: (1) uncertainty in the coefficients (as defined by the regression standard error estimate), and

⁸³ Uncertainty is assumed to be higher for the GHGRP-Only category, because 2011 is the first year that those utilities have reported to EPA.

(2) the uncertainty in total transmission miles for Non-Reporters. Uncertainties were also estimated regarding (1) the quantity of SF₆ supplied with equipment by equipment manufacturers, which is projected from Partner provided nameplate capacity data and industry SF₆ nameplate capacity estimates, and (2) the manufacturers' SF₆ emissions rate.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 4-103. Electrical Transmission and Distribution SF₆ emissions were estimated to be between 4.6 and 6.9 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range of approximately 17 percent below and 23 percent above the emission estimate of 5.6 MMT CO₂ Eq.

Table 4-103: Approach 2 Quantitative Uncertainty Estimates for SF₆ Emissions from Electrical Transmission and Distribution (MMT CO₂ Eq. and Percent)

Source	Gas	2014 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to 2014 Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Electrical Transmission and Distribution	SF ₆	5.6	4.6	6.9	-17%	+23%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

In addition to the uncertainty quantified above, there is uncertainty associated with using global SF₆ sales data to estimate U.S. emission trends from 1990 through 1999. However, the trend in global emissions implied by sales of SF₆ appears to reflect the trend in global emissions implied by changing SF₆ concentrations in the atmosphere. That is, emissions based on global sales declined by 29 percent between 1995 and 1998 (RAND 2004), and emissions based on atmospheric measurements declined by 17 percent over the same period (Levin et al. 2010).

Several pieces of evidence indicate that U.S. SF₆ emissions were reduced as global emissions were reduced. First, the decreases in sales and emissions coincided with a sharp increase in the price of SF₆ that occurred in the mid-1990s and that affected the United States as well as the rest of the world. A representative from DILO, a major manufacturer of SF₆ recycling equipment, stated that most U.S. utilities began recycling rather than venting SF₆ within two years of the price rise. Finally, the emissions reported by the one U.S. utility that reported its emissions for all the years from 1990 through 1999 under the Partnership showed a downward trend beginning in the mid-1990s.

Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2014. Details on the emission trends through time are described in more detail in the Methodology section, above.

Recalculations Discussion

The historical emissions estimated for this source category have undergone some revisions. SF₆ emission estimates for the period 1990 through 2014 were updated relative to the previous report based on revisions to interpolated and extrapolated non-reported Partner data.⁸⁴ For the current Inventory, historical estimates for the period 2011 through 2014 were also updated relative to the previous report based on revisions to reported historical data in EPA's GHGRP. The regression coefficients to estimate emissions from non-reporting utilities was adjusted between the years 1999 and 2014 due to methodology updates,⁸⁵ and as a result, there were changes to the emissions from non-reporting utilities. Emissions estimates for OEMs were updated to incorporate Subpart SS reported emissions and assumptions on the percent share of emissions from EPA's GHGRP reporters.

⁸⁴ The earlier year estimates within the time series (i.e., 1990-1998) were updated based on revisions to the 1999 U.S. emission estimate because emissions for 1990-1998 are estimated by multiplying a series of annual factors by the estimated U.S. emissions of SF₆ from electric power systems in 1999 (see Methodology section).

⁸⁵ This year, a statistical test was performed to evaluate the difference between "large" and "non-large" reporters. It was determined that there is no statistically significant between the two groups. The regression analysis conducted for estimating non-reporter emissions estimates was updated to remove the "large" versus "non-large" designation.

1 As a result of the recalculations, SF₆ emissions from electrical transmission and distribution decreased by 14 percent
2 for 2014 relative to the previous report. On average, the change in SF₆ emission estimates for the entire time series is
3 approximately 14 percent per year.

4 Planned Improvements

5 EPA is continuing research to improve the methodology for estimating non-reporter nameplate capacity. The current
6 methodology uses Beginning of Year Nameplate Capacity and the Net Increase in Nameplate Capacity for the
7 GHGRP-only reporters, which aggregates a small portion of hermetically sealed equipment and high-voltage
8 equipment. More research is needed to determine the impact of removing the Net Increase in Nameplate Capacity.

9 4.25 Nitrous Oxide from Product Uses (IPCC 10 Source Category 2G3)

11 Nitrous oxide (N₂O) is a clear, colorless, oxidizing liquefied gas, with a slightly sweet odor which is used in a wide
12 variety of specialized product uses and applications. The amount of N₂O that is actually emitted depends upon the
13 specific product use or application.

14 There are a total of three N₂O production facilities currently operating in the United States (Ottinger 2014). Nitrous
15 oxide is primarily used in carrier gases with oxygen to administer more potent inhalation anesthetics for general
16 anesthesia, and as an anesthetic in various dental and veterinary applications. The second main use of N₂O is as a
17 propellant in pressure and aerosol products, the largest application being pressure-packaged whipped cream. Small
18 quantities of N₂O also are used in the following applications:

- 19 • Oxidizing agent and etchant used in semiconductor manufacturing;
- 20 • Oxidizing agent used, with acetylene, in atomic absorption spectrometry;
- 21 • Production of sodium azide, which is used to inflate airbags;
- 22 • Fuel oxidant in auto racing; and
- 23 • Oxidizing agent in blowtorches used by jewelers and others (Heydorn 1997).

24 Production of N₂O in 2015 was approximately 15 kt (see Table 4-104).

25 **Table 4-104: N₂O Production (kt)**

Year	kt
1990	16
2005	15
2011	15
2012	15
2013	15
2014	15
2015	15

26 Nitrous oxide emissions were 4.2 MMT CO₂ Eq. (14 kt N₂O) in 2015 (see Table 4-105). Production of N₂O
27 stabilized during the 1990s because medical markets had found other substitutes for anesthetics, and more medical
28 procedures were being performed on an outpatient basis using local anesthetics that do not require N₂O. The use of
29 N₂O as a propellant for whipped cream has also stabilized due to the increased popularity of cream products
30 packaged in reusable plastic tubs (Heydorn 1997).

1 **Table 4-105: N₂O Emissions from N₂O Product Usage (MMT CO₂ Eq. and kt)**

Year	MMT CO ₂ Eq.	kt
1990	4.2	14
2005	4.2	14
2011	4.2	14
2012	4.2	14
2013	4.2	14
2014	4.2	14
2015	4.2	14

2 Methodology

3 Emissions from N₂O product uses were estimated using the following equation:

$$4 \quad E_{pu} = \sum_a (P \times S_a \times ER_a)$$

5 where,

6	E_{pu}	=	N ₂ O emissions from product uses, metric tons
7	P	=	Total U.S. production of N ₂ O, metric tons
8	a	=	specific application
9	S_a	=	Share of N ₂ O usage by application a
10	ER_a	=	Emission rate for application a , percent

11 The share of total quantity of N₂O usage by end-use represents the share of national N₂O produced that is used by
 12 the specific subcategory (e.g., anesthesia, food processing). In 2015, the medical/dental industry used an estimated
 13 86.5 percent of total N₂O produced, followed by food processing propellants at 6.5 percent. All other categories
 14 combined used the remainder of the N₂O produced. This subcategory breakdown has changed only slightly over the
 15 past decade. For instance, the small share of N₂O usage in the production of sodium azide has declined significantly
 16 during the 1990s. Due to the lack of information on the specific time period of the phase-out in this market
 17 subcategory, most of the N₂O usage for sodium azide production is assumed to have ceased after 1996, with the
 18 majority of its small share of the market assigned to the larger medical/dental consumption subcategory (Heydorn
 19 1997). The N₂O was allocated across the following categories: medical applications, food processing propellant, and
 20 sodium azide production (pre-1996). A usage emissions rate was then applied for each sector to estimate the amount
 21 of N₂O emitted.

22 Only the medical/dental and food propellant subcategories were estimated to release emissions into the atmosphere,
 23 and therefore these subcategories were the only usage subcategories with emission rates. For the medical/dental
 24 subcategory, due to the poor solubility of N₂O in blood and other tissues, none of the N₂O is assumed to be
 25 metabolized during anesthesia and quickly leaves the body in exhaled breath. Therefore, an emission factor of 100
 26 percent was used for this subcategory (IPCC 2006). For N₂O used as a propellant in pressurized and aerosol food
 27 products, none of the N₂O is reacted during the process and all of the N₂O is emitted to the atmosphere, resulting in
 28 an emission factor of 100 percent for this subcategory (IPCC 2006). For the remaining subcategories, all of the N₂O
 29 is consumed/reacted during the process, and therefore the emission rate was considered to be zero percent (Tupman
 30 2002).

31 The 1990 through 1992 N₂O production data were obtained from SRI Consulting's *Nitrous Oxide, North America*
 32 report (Heydorn 1997). Nitrous oxide production data for 1993 through 1995 were not available. Production data for
 33 1996 was specified as a range in two data sources (Heydorn 1997; Tupman 2002). In particular, for 1996, Heydorn
 34 (1997) estimates N₂O production to range between 13.6 and 18.1 thousand metric tons. Tupman (2003) provided a
 35 narrower range (15.9 to 18.1 thousand metric tons) for 1996 that falls within the production bounds described by
 36 Heydorn (1997). Tupman (2003) data are considered more industry-specific and current. Therefore, the midpoint of
 37 the narrower production range was used to estimate N₂O emissions for years 1993 through 2001 (Tupman 2003).

1 The 2002 and 2003 N₂O production data were obtained from the Compressed Gas Association Nitrous Oxide Fact
 2 Sheet and Nitrous Oxide Abuse Hotline (CGA 2002, 2003). These data were also provided as a range. For example,
 3 in 2003, CGA (2003) estimates N₂O production to range between 13.6 and 15.9 thousand metric tons. Due to the
 4 unavailability of data, production estimates for years 2004 through 2015 were held constant at the 2003 value.

5 The 1996 share of the total quantity of N₂O used by each subcategory was obtained from SRI Consulting's *Nitrous*
 6 *Oxide, North America* report (Heydorn 1997). The 1990 through 1995 share of total quantity of N₂O used by each
 7 subcategory was kept the same as the 1996 number provided by SRI Consulting. The 1997 through 2001 share of
 8 total quantity of N₂O usage by sector was obtained from communication with a N₂O industry expert (Tupman 2002).
 9 The 2002 and 2003 share of total quantity of N₂O usage by sector was obtained from CGA (2002, 2003). Due to the
 10 unavailability of data, the share of total quantity of N₂O usage data for years 2004 through 2015 was assumed to
 11 equal the 2003 value. The emissions rate for the food processing propellant industry was obtained from SRI
 12 Consulting's *Nitrous Oxide, North America* report (Heydorn 1997), and confirmed by a N₂O industry expert
 13 (Tupman 2002). The emissions rate for all other subcategories was obtained from communication with a N₂O
 14 industry expert (Tupman 2002). The emissions rate for the medical/dental subcategory was obtained from the 2006
 15 *IPCC Guidelines*.

16 **Uncertainty and Time-Series Consistency – TO BE UPDATED**

17 **FOR FINAL INVENTORY REVIEW**

18 The overall uncertainty associated with the 2015 N₂O emission estimate from N₂O product usage was calculated
 19 using the 2006 *IPCC Guidelines* (2006) Approach 2 methodology. Uncertainty associated with the parameters used
 20 to estimate N₂O emissions include production data, total market share of each end use, and the emission factors
 21 applied to each end use, respectively.

22 The results of this Approach 2 quantitative uncertainty analysis are summarized in Table 4-106. Nitrous oxide
 23 emissions from N₂O product usage were estimated to be between 3.2 and 5.2 MMT CO₂ Eq. at the 95 percent
 24 confidence level. This indicates a range of approximately 24 percent below to 24 percent above the emission
 25 estimate of 4.2 MMT CO₂ Eq.

26 **Table 4-106: Approach 2 Quantitative Uncertainty Estimates for N₂O Emissions from N₂O**
 27 **Product Usage (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
N ₂ O from Product Uses	N ₂ O	4.2	3.2	5.2	-24%	+24%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

28 Methodological recalculations were applied to the entire time series to ensure consistency in emissions from 1990
 29 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 30 above.

31 **Planned Improvements**

32 Pending resources, planned improvements include a continued evaluation of alternative production statistics for
 33 cross verification, a reassessment of N₂O product use subcategories to accurately represent trends, investigation of
 34 production and use cycles, and the potential need to incorporate a time lag between production and ultimate product
 35 use and resulting release of N₂O. Additionally, planned improvements include considering imports and exports of
 36 N₂O for product uses. Finally, for future Inventories EPA will examine data from EPA's GHGRP to improve the
 37 emission estimates for the N₂O product use subcategory. Particular attention will be made to ensure aggregated
 38 information can be published without disclosing CBI and time series consistency, as the facility-level reporting data
 39 from EPA's GHGRP are not available for all inventory years as required in this Inventory. EPA is still assessing the

1 possibility of incorporating aggregated CBI data to estimate emissions; however, this planned improvement is still in
 2 development and not incorporated in the current inventory report.

3 4.26 Industrial Processes and Product Use

4 Sources of Indirect Greenhouse Gases

5 In addition to the main greenhouse gases addressed above, many industrial processes can result in emissions of
 6 various ozone precursors (i.e., indirect greenhouse gases). As some of industrial applications also employ thermal
 7 incineration as a control technology, combustion byproducts, such as carbon monoxide (CO) and nitrogen oxides
 8 (NO_x), are also reported with this source category. Non-CH₄ volatile organic compounds (NMVOCs), commonly
 9 referred to as “hydrocarbons,” are the primary gases emitted from most processes employing organic or petroleum
 10 based products, and can also result from the product storage and handling. Accidental releases of greenhouse gases
 11 associated with product use and handling can constitute major emissions in this category. In the United States,
 12 emissions from product use are primarily the result of solvent evaporation, whereby the lighter hydrocarbon
 13 molecules in the solvents escape into the atmosphere. The major categories of product uses include: degreasing,
 14 graphic arts, surface coating, other industrial uses of solvents (e.g., electronics), dry cleaning, and non-industrial
 15 uses (e.g., uses of paint thinner). Product usage in the United States also results in the emission of small amounts of
 16 hydrofluorocarbons (HFCs) and hydrofluoroethers (HFEs), which are included under Substitution of Ozone
 17 Depleting Substances in this chapter.

18 Total emissions of NO_x, CO, and NMVOCs from non-energy industrial processes and product use from 1990 to
 19 2015 are reported in Table 4-107.

20 **Table 4-107: NO_x, CO, and NMVOC Emissions from Industrial Processes and Product Use (kt)**

^a Miscellaneous includes the following categories: catastrophic/accidental release, other combustion, health services, cooling towers, and fugitive dust. It does not include agricultural fires or slash/prescribed burning, which are accounted for under the Field Burning of Agricultural Residues source.

^b Includes rubber and plastics manufacturing, and other miscellaneous applications.

^c Includes cutback asphalt, pesticide application adhesives, consumer solvents, and other miscellaneous applications.

Note: Totals may not sum due to independent rounding.

1 Methodology

2 Emission estimates for 1990 through 2015 were obtained from data published on the National Emission Inventory
3 (NEI) Air Pollutant Emission Trends web site (EPA 2016), and disaggregated based on EPA (2003). Data were
4 collected for emissions of CO, NO_x, volatile organic compounds (VOCs), and sulfur dioxide (SO₂) from metals
5 processing, chemical manufacturing, other industrial processes, transport and storage, and miscellaneous sources.
6 Emission estimates for 2012 and 2013 for non-electric generating units (EGU) are held constant from 2011 in EPA
7 (2016). Emission estimates for 2012 and 2013 for non-mobile sources are recalculated emissions by interpolation
8 from 2015 in EPA (2016). Emissions were calculated either for individual source categories or for many categories
9 combined, using basic activity data (e.g., the amount of raw material processed or the amount of solvent purchased)
10 as an indicator of emissions. National activity data were collected for individual categories from various agencies.
11 Depending on the category, these basic activity data may include data on production, fuel deliveries, raw material
12 processed, etc.

13 Emissions for product use were calculated by aggregating product use data based on information relating to product
14 uses from different applications such as degreasing, graphic arts, etc. Emission factors for each consumption
15 category were then applied to the data to estimate emissions. For example, emissions from surface coatings were
16 mostly due to solvent evaporation as the coatings solidify. By applying the appropriate product-specific emission
17 factors to the amount of products used for surface coatings, an estimate of NMVOC emissions was obtained.
18 Emissions of CO and NO_x under product use result primarily from thermal and catalytic incineration of solvent-
19 laden gas streams from painting booths, printing operations, and oven exhaust.

20 Activity data were used in conjunction with emission factors, which together relate the quantity of emissions to the
21 activity. Emission factors are generally available from the EPA's *Compilation of Air Pollutant Emission Factors*,
22 AP-42 (EPA 1997). The EPA currently derives the overall emission control efficiency of a source category from a
23 variety of information sources, including published reports, the 1985 National Acid Precipitation and Assessment
24 Program emissions inventory, and other EPA databases.

1 **Uncertainty and Time-Series Consistency**

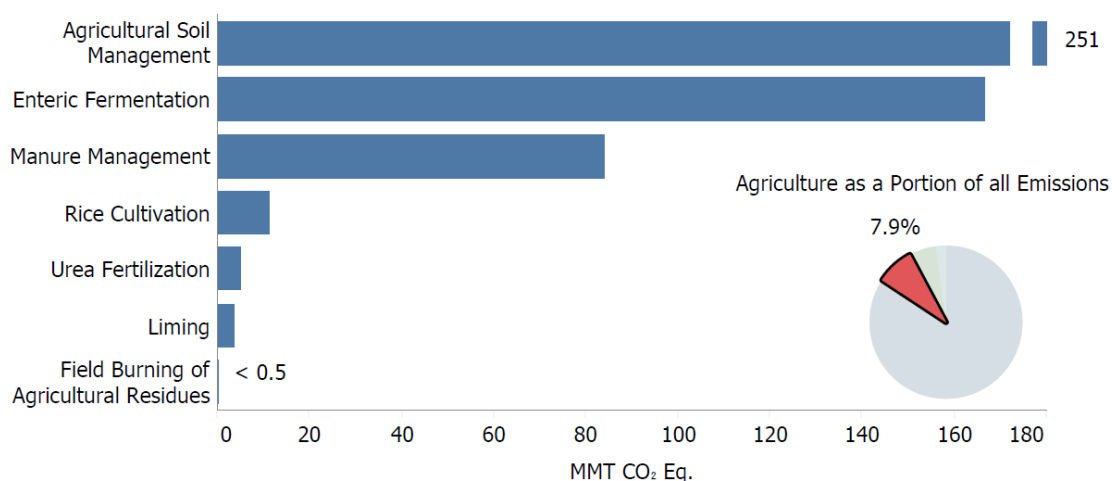

2 Uncertainties in these estimates are partly due to the accuracy of the emission factors and activity data used. A
3 quantitative uncertainty analysis was not performed.

4 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
5 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
6 above.
7

5. Agriculture

Agricultural activities contribute directly to emissions of greenhouse gases through a variety of processes. This chapter provides an assessment of non-carbon dioxide (CO₂) emissions from the following source categories: enteric fermentation in domestic livestock, livestock manure management, rice cultivation, agricultural soil management, and field burning of agricultural residues, as well as CO₂ emissions from liming and urea fertilization (see Figure 5-1). Additional CO₂ emissions and removals from agriculture-related land-use and management activities, such as cultivation of cropland and conversion of grassland to cropland, are presented in the Land Use, Land-Use Change, and Forestry chapter. Carbon dioxide emissions from on-farm energy use are accounted for in the Energy chapter.

Figure 5-1: 2015 Agriculture Chapter Greenhouse Gas Emission Sources (MMT CO₂ Eq.)

In 2015, the Agriculture sector was responsible for emissions of 522.3 MMT CO₂ Eq.,¹ or 7.9 percent of total U.S. greenhouse gas emissions. Carbon dioxide, methane (CH₄), and nitrous oxide (N₂O) were the primary greenhouse gases emitted by agricultural activities. Methane emissions from enteric fermentation and manure management represent 25.4 percent and 10.1 percent of total CH₄ emissions from anthropogenic activities, respectively. Of all domestic animal types, beef and dairy cattle were by far the largest emitters of CH₄. Rice cultivation and field burning of agricultural residues were minor sources of CH₄. Emissions of N₂O by agricultural soil management through activities such as fertilizer application and other agricultural practices that increased nitrogen availability in the soil were the largest source of U.S. N₂O emissions, accounting for 75.0 percent. Manure management and field burning of agricultural residues were also small sources of N₂O emissions. Urea fertilization and liming each accounted for 0.1 percent of total CO₂ emissions from anthropogenic activities.

¹ Following the current reporting requirements under the United Nations Framework Convention on Climate Change (UNFCCC), this Inventory report presents CO₂ equivalent values based on the *IPCC Fourth Assessment Report (AR4)* GWP values. See the Introduction chapter for more information.

1 Table 5-1 and Table 5-2 present emission estimates for the Agriculture sector. Between 1990 and 2015, CO₂ and
 2 CH₄ emissions from agricultural activities increased by 24.8 percent and 12.3 percent, respectively, while N₂O
 3 emissions fluctuated from year to year, but overall decreased by 0.6 percent.

4 **Table 5-1: Emissions from Agriculture (MMT CO₂ Eq.)**

Gas/Source	1990	2005	2011	2012	2013	2014	2015

6

7 5.1 Enteric Fermentation (IPCC Source 8 Category 3A)

9 Methane is produced as part of normal digestive processes in animals. During digestion, microbes resident in an
 10 animal's digestive system ferment food consumed by the animal. This microbial fermentation process, referred to as
 11 enteric fermentation, produces CH₄ as a byproduct, which can be exhaled or eructated by the animal. The amount of
 12 CH₄ produced and emitted by an individual animal depends primarily upon the animal's digestive system, and the
 13 amount and type of feed it consumes.

14 Ruminant animals (e.g., cattle, buffalo, sheep, goats, and camels) are the major emitters of CH₄ because of their
 15 unique digestive system. Ruminants possess a rumen, or large "fore-stomach," in which microbial fermentation
 16 breaks down the feed they consume into products that can be absorbed and metabolized. The microbial fermentation

1 that occurs in the rumen enables them to digest coarse plant material that non-ruminant animals cannot. Ruminant
2 animals, consequently, have the highest CH₄ emissions per unit of body mass among all animal types.

3 Non-ruminant animals (e.g., swine, horses, and mules and asses) also produce CH₄ emissions through enteric
4 fermentation, although this microbial fermentation occurs in the large intestine. These non-ruminants emit
5 significantly less CH₄ on a per-animal-mass basis than ruminants because the capacity of the large intestine to
6 produce CH₄ is lower.

7 In addition to the type of digestive system, an animal's feed quality and feed intake also affect CH₄ emissions. In
8 general, lower feed quality and/or higher feed intake leads to higher CH₄ emissions. Feed intake is positively
9 correlated to animal size, growth rate, level of activity and production (e.g., milk production, wool growth,
10 pregnancy, or work). Therefore, feed intake varies among animal types as well as among different management
11 practices for individual animal types (e.g., animals in feedlots or grazing on pasture).

12 Methane emission estimates from enteric fermentation are provided in Table 5-3 and Table 5-4. Total livestock CH₄
13 emissions in 2015 were 166.5 MMT CO₂ Eq. (6,661 kt). Beef cattle remain the largest contributor of CH₄ emissions
14 from enteric fermentation, accounting for 71 percent in 2015. Emissions from dairy cattle in 2015 accounted for 26
15 percent, and the remaining emissions were from horses, sheep, swine, goats, American bison, mules and asses.

16 **Table 5-3: CH₄ Emissions from Enteric Fermentation (MMT CO₂ Eq.)**

Livestock Type	1990	2005	2011	2012	2013	2014	2015
Beef Cattle	119.1	125.2	121.8	119.1	118.0	116.5	118.1
Dairy Cattle	39.4	37.6	41.1	41.7	41.6	42.0	42.6

Total	6,566	6,755	6,757	6,670	6,619	6,567	6,661

Note: Totals may not sum due to independent rounding.

19 From 1990 to 2015, emissions from enteric fermentation have increased by 1.5 percent. While emissions generally
20 follow trends in cattle populations, over the long term there are exceptions as population decreases have been
21 coupled with production increases or minor decreases. For example, beef cattle emissions decreased 0.8 percent
22 from 1990 to 2015, while beef cattle populations actually declined by 7 percent and beef production increased
23 (USDA 2016), and while dairy emissions increased 8.3 percent over the entire time series, the population has
24 declined by 4 percent and milk production increased 40 percent (USDA 2016). This trend indicates that while
25 emission factors per head are increasing, emission factors per unit of product are going down.

26 Generally, from 1990 to 1995 emissions from beef increased and then decreased from 1996 to 2004. These trends
27 were mainly due to fluctuations in beef cattle populations and increased digestibility of feed for feedlot cattle. Beef
28 cattle emissions generally increased from 2004 to 2007, as beef populations underwent increases and an extensive

1 literature review indicated a trend toward a decrease in feed digestibility for those years. Beef cattle emissions
2 decreased again from 2008 to 2015 as populations again decreased. Emissions from dairy cattle generally trended
3 downward from 1990 to 2004, along with an overall dairy population decline during the same period. Similar to beef
4 cattle, dairy cattle emissions rose from 2004 to 2007 due to population increases and a decrease in feed digestibility
5 (based on an analysis of more than 350 dairy cow diets). Dairy cattle emissions have continued to trend upward
6 since 2007, in line with dairy population increases. Regarding trends in other animals, populations of sheep have
7 steadily declined, with an overall decrease of 54 percent since 1990. Horse populations are 56 percent greater than
8 they were in 1990, but their numbers have been declining by about 2 percent annually since 2007. Goat populations
9 increased by about 20 percent through 2007 but have since dropped below 1990 numbers, while swine populations
10 have increased 19 percent since 1990. The population of American bison more than tripled over the 1990-2015 time
11 period, while mules and asses have more than quadrupled.

12 Methodology

13 Livestock enteric fermentation emission estimate methodologies fall into two categories: cattle and other
14 domesticated animals. Cattle, due to their large population, large size, and particular digestive characteristics,
15 account for the majority of enteric fermentation CH₄ emissions from livestock in the United States. A more detailed
16 methodology (i.e., IPCC Tier 2) was therefore applied to estimate emissions for all cattle. Emission estimates for
17 other domesticated animals (horses, sheep, swine, goats, American bison, and mules and asses) were handled using a
18 less detailed approach (i.e., IPCC Tier 1).

19 While the large diversity of animal management practices cannot be precisely characterized and evaluated,
20 significant scientific literature exists that provides the necessary data to estimate cattle emissions using the IPCC
21 Tier 2 approach. The Cattle Enteric Fermentation Model (CEFM), developed by EPA and used to estimate cattle
22 CH₄ emissions from enteric fermentation, incorporates this information and other analyses of livestock population,
23 feeding practices, and production characteristics.

24 National cattle population statistics were disaggregated into the following cattle sub-populations:

- 25 • Dairy Cattle
 - 26 ○ Calves
 - 27 ○ Heifer Replacements
 - 28 ○ Cows
- 29 • Beef Cattle
 - 30 ○ Calves
 - 31 ○ Heifer Replacements
 - 32 ○ Heifer and Steer Stockers
 - 33 ○ Animals in Feedlots (Heifers and Steer)
 - 34 ○ Cows
 - 35 ○ Bulls

36 Calf birth rates, end-of-year population statistics, detailed feedlot placement information, and slaughter weight data
37 were used to create a transition matrix that models cohorts of individual animal types and their specific emission
38 profiles. The key variables tracked for each of the cattle population categories are described in Annex 3.10. These
39 variables include performance factors such as pregnancy and lactation as well as average weights and weight gain.
40 Annual cattle population data were obtained from the U.S. Department of Agriculture's (USDA) National
41 Agricultural Statistics Service (NASS) *QuickStats* database (USDA 2016).

42 Diet characteristics were estimated by region for dairy, foraging beef, and feedlot beef cattle. These diet
43 characteristics were used to calculate digestible energy (DE) values (expressed as the percent of gross energy intake
44 digested by the animal) and CH₄ conversion rates (Y_m) (expressed as the fraction of gross energy converted to CH₄)
45 for each regional population category. The IPCC recommends Y_m ranges of 3.0±1.0 percent for feedlot cattle and

1 6.5±1.0 percent for other well-fed cattle consuming temperate-climate feed types (IPCC 2006). Given the
2 availability of detailed diet information for different regions and animal types in the United States, DE and Y_m
3 values unique to the United States were developed. The diet characterizations and estimation of DE and Y_m values
4 were based on information from state agricultural extension specialists, a review of published forage quality studies
5 and scientific literature, expert opinion, and modeling of animal physiology.

6 The diet characteristics for dairy cattle were based on Donovan (1999) and an extensive review of nearly 20 years of
7 literature from 1990 through 2009. Estimates of DE were national averages based on the feed components of the
8 diets observed in the literature for the following year groupings: 1990-1993, 1994-1998, 1999-2003, 2004-2006,
9 2007, and 2008 onward.² Base year Y_m values by region were estimated using Donovan (1999). As described in
10 ERG (2016), a ruminant digestion model (COWPOLL, as selected in Kebreab et al. 2008) was used to evaluate Y_m
11 for each diet evaluated from the literature, and a function was developed to adjust regional values over time based
12 on the national trend. Dairy replacement heifer diet assumptions were based on the observed relationship in the
13 literature between dairy cow and dairy heifer diet characteristics.

14 For feedlot animals, the DE and Y_m values used for 1990 were recommended by Johnson (1999). Values for DE and
15 Y_m for 1991 through 1999 were linearly extrapolated based on the 1990 and 2000 data. DE and Y_m values for 2000
16 onwards were based on survey data in Galyean and Gleghorn (2001) and Vasconcelos and Galyean (2007).

17 For grazing beef cattle, Y_m values were based on Johnson (2002), DE values for 1990 through 2006 were based on
18 specific diet components estimated from Donovan (1999), and DE values from 2007 onwards were developed from
19 an analysis by Archibeque (2011), based on diet information in Preston (2010) and USDA-APHIS:VS (2010).
20 Weight and weight gains for cattle were estimated from Holstein (2010), Doren et al. (1989), Enns (2008), Lippke et
21 al. (2000), Pinchack et al. (2004), Platter et al. (2003), Skogerboe et al. (2000), and expert opinion. See Annex 3.10
22 for more details on the method used to characterize cattle diets and weights in the United States.

23 Calves younger than 4 months are not included in emission estimates because calves consume mainly milk and the
24 IPCC recommends the use of a Y_m of zero for all juveniles consuming only milk. Diets for calves aged 4 to 6
25 months are assumed to go through a gradual weaning from milk decreasing to 75 percent at 4 months, 50 percent at
26 age 5 months, and 25 percent at age 6 months. The portion of the diet made up with milk still results in zero
27 emissions. For the remainder of the diet, beef calf DE and Y_m are set equivalent to those of beef replacement heifers,
28 while dairy calf DE is set equal to that of dairy replacement heifers and dairy calf Y_m is provided at 4 and 7 months
29 of age by Soliva (2006). Estimates of Y_m for 5 and 6 month old dairy calves are linearly interpolated from the values
30 provided for 4 and 7 months.

31 To estimate CH₄ emissions, the population was divided into state, age, sub-type (i.e., dairy cows and replacements,
32 beef cows and replacements, heifer and steer stockers, heifers and steers in feedlots, bulls, beef calves 4 to 6 months,
33 and dairy calves 4 to 6 months), and production (i.e., pregnant, lactating) groupings to more fully capture differences
34 in CH₄ emissions from these animal types. The transition matrix was used to simulate the age and weight structure
35 of each sub-type on a monthly basis in order to more accurately reflect the fluctuations that occur throughout the
36 year. Cattle diet characteristics were then used in conjunction with Tier 2 equations from IPCC (2006) to produce
37 CH₄ emission factors for the following cattle types: dairy cows, beef cows, dairy replacements, beef replacements,
38 steer stockers, heifer stockers, steer feedlot animals, heifer feedlot animals, bulls, and calves. To estimate emissions
39 from cattle, monthly population data from the transition matrix were multiplied by the calculated emission factor for
40 each cattle type. More details are provided in Annex 3.10.

41 Emission estimates for other animal types were based on average emission factors representative of entire
42 populations of each animal type. Methane emissions from these animals accounted for a minor portion of total CH₄
43 emissions from livestock in the United States from 1990 through 2015. Additionally, the variability in emission
44 factors for each of these other animal types (e.g., variability by age, production system, and feeding practice within
45 each animal type) is less than that for cattle. Annual livestock population data for sheep; swine; goats; horses; mules
46 and asses; and American bison were obtained for available years from USDA NASS (USDA 2016). Horse, goat and
47 mule and ass population data were available for 1987, 1992, 1997, 2002, 2007, and 2012 (USDA 1992, 1997, 2016);
48 the remaining years between 1990 and 2015 were interpolated and extrapolated from the available estimates (with
49 the exception of goat populations being held constant between 1990 and 1992). American bison population

² Due to inconsistencies in the 2003 literature values, the 2002 values were used for 2003, as well.

estimates were available from USDA for 2002, 2007, and 2012 (USDA 2016) and from the National Bison Association (1999) for 1990 through 1999. Additional years were based on observed trends from the National Bison Association (1999), interpolation between known data points, and extrapolation beyond 2012, as described in more detail in Annex 3.10. Methane emissions from sheep, goats, swine, horses, American bison, and mules and asses were estimated by using emission factors utilized in Crutzen et al. (1986, cited in IPCC 2006). These emission factors are representative of typical animal sizes, feed intakes, and feed characteristics in developed countries. For American bison the emission factor for buffalo was used and adjusted based on the ratio of live weights to the 0.75 power. The methodology is the same as that recommended by IPCC (2006).

See Annex 3.10 for more detailed information on the methodology and data used to calculate CH₄ emissions from enteric fermentation.

Uncertainty and Time-Series Consistency

A quantitative uncertainty analysis for this source category was performed using the IPCC-recommended Approach 2 uncertainty estimation methodology based on a Monte Carlo Stochastic Simulation technique as described in ICF (2003). These uncertainty estimates were developed for the 1990 through 2001 Inventory report (i.e., 2003 submission to the UNFCCC). There have been no significant changes to the methodology since that time; consequently, these uncertainty estimates were directly applied to the 2015 emission estimates in this Inventory report.

A total of 185 primary input variables (177 for cattle and 8 for non-cattle) were identified as key input variables for the uncertainty analysis. A normal distribution was assumed for almost all activity- and emission factor-related input variables. Triangular distributions were assigned to three input variables (specifically, cow-birth ratios for the three most recent years included in the 2001 model run) to ensure only positive values would be simulated. For some key input variables, the uncertainty ranges around their estimates (used for inventory estimation) were collected from published documents and other public sources; others were based on expert opinion and best estimates. In addition, both endogenous and exogenous correlations between selected primary input variables were modeled. The exogenous correlation coefficients between the probability distributions of selected activity-related variables were developed through expert judgment.

The uncertainty ranges associated with the activity data-related input variables were plus or minus 10 percent or lower. However, for many emission factor-related input variables, the lower- and/or the upper-bound uncertainty estimates were over 20 percent. The results of the quantitative uncertainty analysis are summarized in Table 5-5. Based on this analysis, enteric fermentation CH₄ emissions in 2015 were estimated to be between 148.2 and 196.5 MMT CO₂ Eq. at a 95 percent confidence level, which indicates a range of 11 percent below to 18 percent above the 2015 emission estimate of 166.5 MMT CO₂ Eq. Among the individual cattle sub-source categories, beef cattle account for the largest amount of CH₄ emissions, as well as the largest degree of uncertainty in the emission estimates—due mainly to the difficulty in estimating the diet characteristics for grazing members of this animal group. Among non-cattle, horses represent the largest percent of uncertainty in the previous uncertainty analysis because the Food and Agricultural Organization of the United Nations (FAO) population estimates used for horses at that time had a higher degree of uncertainty than for the USDA population estimates used for swine, goats, and sheep. The horse populations are now from the same USDA source as the other animal types, and therefore the uncertainty range around horses is likely overestimated. Cattle calves, American bison, mules and asses were excluded from the initial uncertainty estimate because they were not included in emission estimates at that time.

Table 5-5: Approach 2 Quantitative Uncertainty Estimates for CH₄ Emissions from Enteric Fermentation (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^{a, b, c}			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Enteric Fermentation	CH ₄	166.5	148.2	196.5	-11%	+18%

^a Range of emissions estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

^b Note that the relative uncertainty range was estimated with respect to the 2001 emission estimates from the 2003 submission and applied to the 2015 estimates.

^c The overall uncertainty calculated in 2003, and applied to the 2015 emission estimate, did not include uncertainty estimates for calves, American bison, and mules and asses. Additionally, for bulls the emissions estimate was based on the Tier 1 methodology. Since bull emissions are now estimated using the Tier 2 method, the uncertainty surrounding their estimates is likely lower than indicated by the previous uncertainty analysis.

1 Methodological recalculations were applied to the entire time series to ensure time-series consistency from 1990
2 through 2015. Details on the emission trends through time are described in more detail in the Methodology section.

3 QA/QC and Verification

4 In order to ensure the quality of the emission estimates from enteric fermentation, the IPCC Tier 1 and Tier 2
5 Quality Assurance/Quality Control (QA/QC) procedures were implemented consistent with the U.S. QA/QC plan
6 (EPA 2002). Tier 2 QA procedures included independent peer review of emission estimates. Over the past few
7 years, particular importance has been placed on harmonizing the data exchange between the enteric fermentation
8 and manure management source categories. The current Inventory now utilizes the transition matrix from the CEFM
9 for estimating cattle populations and weights for both source categories, and the CEFM is used to output volatile
10 solids and nitrogen excretion estimates using the diet assumptions in the model in conjunction with the energy
11 balance equations from the IPCC (2006). This approach facilitates the QA/QC process for both of these source
12 categories.

13 Recalculations Discussion

14 For the current Inventory, differences can be seen in emission estimates for years prior to 2015 when compared
15 against the same years in the previous Inventory—from 2008 through 2011, as well as 2014. These recalculations
16 were due to changes made to historical data and corrections made to erroneous formulas in the CEFM. No
17 modifications were made to the methodology.

18 Revisions to input data include the following:

- 19 • The USDA published minor revisions in several categories that affected historical emissions estimated for cattle
20 for 2008 and subsequent years, including the following:
 - 21 ○ Calf birth data were revised for 2008 and 2014;
 - 22 ○ Dairy cow milk production values were revised for several states for 2014;
 - 23 ○ Slaughter values were revised for 2014 for steers and heifers;
- 24 • The USDA also revised population estimates for some categories of non-cattle animals, which affected
25 historical emissions estimated for “other” livestock. Changes included:
 - 26 ○ Revised 2014 populations for market and breeding swine in some states; and
 - 27 ○ Revised 2013 populations of sheep for some states.

28 In addition to these changes in input data, a miscount of the number of states included in the cattle on feed total for
29 “other states” in 2011 was corrected. This resulted in revised 2011 estimates for feedlot cattle in 19 states.

30 These recalculations had an insignificant impact on the overall emission estimates.

31 Planned Improvements

32 Continued research and regular updates are necessary to maintain an emissions inventory that reflects the current
33 base of knowledge. Future improvements for enteric fermentation could include some of the following options:

- 34 • Further research to improve the estimation of dry matter intake (as gross energy intake) using data from
35 appropriate production systems;

- 1 • Updating input variables that are from older data sources, such as beef births by month and beef cow lactation
2 rates;
- 3 • Investigation of the availability of annual data for the DE, Y_m , and crude protein values of specific diet and feed
4 components for foraging and feedlot animals;
- 5 • Further investigation on additional sources or methodologies for estimating DE for dairy, given the many
6 challenges in characterizing dairy diets;
- 7 • Further evaluation of the assumptions about weights and weight gains for beef cows, such that trends beyond
8 2007 are updated, rather than held constant;
- 9 • Further evaluation of the estimated weight for dairy cows (i.e., 1,500 lbs) that is based solely on Holstein cows
10 as mature dairy cow weight is likely slightly overestimated, based on knowledge of the breeds of dairy cows in
11 the United States;
- 12 • Potentially updating to a Tier 2 methodology for other animal types (i.e., sheep, swine, goats, horses);
- 13 • Investigation of methodologies and emission factors for including enteric fermentation emission estimates from
14 poultry;
- 15 • Comparison of the current CEFM processing of animal population data to estimates developed using annual
16 average populations to determine if the model could be simplified to use annual population data; and
- 17 • Recent changes that have been implemented to the CEFM warrant an assessment of the current uncertainty
18 analysis; therefore, a revision of the quantitative uncertainty surrounding emission estimates from this source
19 category will be initiated.

20 5.2 Manure Management (IPCC Source 21 Category 3B)

22 The treatment, storage, and transportation of livestock manure can produce anthropogenic CH_4 and N_2O emissions.
23 Methane is produced by the anaerobic decomposition of manure. Nitrous oxide emissions are produced through both
24 direct and indirect pathways. Direct N_2O emissions are produced as part of the nitrogen (N) cycle through the
25 nitrification and denitrification of the organic N in livestock dung and urine.³ There are two pathways for indirect
26 N_2O emissions. The first is the result of the volatilization of N in manure (as NH_3 and NO_x) and the subsequent
27 deposition of these gases and their products (NH_4^+ and NO_3^-) onto soils and the surface of lakes and other waters.
28 The second pathway is the runoff and leaching of N from manure to the groundwater below, in riparian zones
29 receiving drain or runoff water, or in the ditches, streams, rivers, and estuaries into which the land drainage water
30 eventually flows.

31 When livestock or poultry manure are stored or treated in systems that promote anaerobic conditions (e.g., as a
32 liquid/slurry in lagoons, ponds, tanks, or pits), the decomposition of the volatile solids component in the manure
33 tends to produce CH_4 . When manure is handled as a solid (e.g., in stacks or drylots) or deposited on pasture, range,
34 or paddock lands, it tends to decompose aerobically and produce little or no CH_4 . Ambient temperature, moisture,
35 and manure storage or residency time affect the amount of CH_4 produced because they influence the growth of the
36 bacteria responsible for CH_4 formation. For non-liquid-based manure systems, moist conditions (which are a
37 function of rainfall and humidity) can promote CH_4 production. Manure composition, which varies by animal diet,
38 growth rate, and type, including the animal's digestive system, also affects the amount of CH_4 produced. In general,
39 the greater the energy content of the feed, the greater the potential for CH_4 emissions. However, some higher-energy

³ Direct and indirect N_2O emissions from dung and urine spread onto fields either directly as daily spread or after it is removed from manure management systems (i.e., lagoon, pit, etc.) and from livestock dung and urine deposited on pasture, range, or paddock lands are accounted for and discussed in the Agricultural Soil Management source category within the Agriculture sector.

1 feeds also are more digestible than lower quality forages, which can result in less overall waste excreted from the
2 animal.

3 The production of direct N₂O emissions from livestock manure depends on the composition of the manure and urine,
4 the type of bacteria involved in the process, and the amount of oxygen and liquid in the manure system. For direct
5 N₂O emissions to occur, the manure must first be handled aerobically where ammonia (NH₃) or organic N is
6 converted to nitrates and nitrites (nitrification), and then handled anaerobically where the nitrates and nitrites are
7 reduced to dinitrogen gas (N₂), with intermediate production of N₂O and nitric oxide (NO) (denitrification)
8 (Groffman et al. 2000). These emissions are most likely to occur in dry manure handling systems that have aerobic
9 conditions, but that also contain pockets of anaerobic conditions due to saturation. A very small portion of the total
10 N excreted is expected to convert to N₂O in the waste management system (WMS). Indirect N₂O emissions are
11 produced when nitrogen is lost from the system through volatilization (as NH₃ or NO_x) or through runoff and
12 leaching. The vast majority of volatilization losses from these operations are NH₃. Although there are also some
13 small losses of NO_x, there are no quantified estimates available for use, so losses due to volatilization are only based
14 on NH₃ loss factors. Runoff losses would be expected from operations that house animals or store manure in a
15 manner that is exposed to weather. Runoff losses are also specific to the type of animal housed on the operation due
16 to differences in manure characteristics. Little information is known about leaching from manure management
17 systems as most research focuses on leaching from land application systems. Since leaching losses are expected to
18 be minimal, leaching losses are coupled with runoff losses and the runoff/leaching estimate provided in this chapter
19 does not account for any leaching losses.

20 Estimates of CH₄ emissions from manure management in 2015 were 66.3 MMT CO₂ Eq. (2,651 kt); in 1990,
21 emissions were 37.2 MMT CO₂ Eq. (1,486 kt). This represents a 78 percent increase in emissions from 1990.
22 Emissions increased on average by 1.1 MMT CO₂ Eq. (3.0 percent) annually over this period. The majority of this
23 increase is due to swine and dairy cow manure, where emissions increased 58 and 136 percent, respectively. From
24 2014 to 2015, there was a 5.4 percent increase in total CH₄ emissions from manure management, mainly due to an
25 increase in larger farms and animal populations, as well a shifting of manure management to liquid systems with
26 increasing farm size.

27 Although the majority of managed manure in the United States is handled as a solid, producing little CH₄, the
28 general trend in manure management, particularly for dairy and swine (which are both shifting towards larger
29 facilities), is one of increasing use of liquid systems. Also, new regulations controlling the application of manure
30 nutrients to land have shifted manure management practices at smaller dairies from daily spread systems to storage
31 and management of the manure on site. Although national dairy animal populations have generally been decreasing
32 since 1990, some states have seen increases in their dairy populations as the industry becomes more concentrated in
33 certain areas of the country and the number of animals contained on each facility increases. These areas of
34 concentration, such as California, New Mexico, and Idaho, tend to utilize more liquid-based systems to manage
35 (flush or scrape) and store manure. Thus the shift toward larger dairy and swine facilities has translated into an
36 increasing use of liquid manure management systems, which have higher potential CH₄ emissions than dry systems.
37 This significant shift in both the dairy and swine industries was accounted for by incorporating state and WMS-
38 specific CH₄ conversion factor (MCF) values in combination with the 1992, 1997, 2002, 2007 and 2012 farm-size
39 distribution data reported in the *Census of Agriculture* (USDA 2016d).

40 In 2015, total N₂O emissions from manure management were estimated to be 17.7 MMT CO₂ Eq. (59 kt); in 1990,
41 emissions were 14.0 MMT CO₂ Eq. (47 kt). These values include both direct and indirect N₂O emissions from
42 manure management. Nitrous oxide emissions have remained fairly steady since 1990. Small changes in N₂O
43 emissions from individual animal groups exhibit the same trends as the animal group populations, with the overall
44 net effect that N₂O emissions showed a 27 percent increase from 1990 to 2015 and a 1.1 percent increase from 2014
45 through 2015. Overall shifts toward liquid systems have driven down the emissions per unit of nitrogen excreted.

46 Table 5-6 and Table 5-7 provide estimates of CH₄ and N₂O emissions from manure management by animal
47 category.

48 **Table 5-6: CH₄ and N₂O Emissions from Manure Management (MMT CO₂ Eq.)**

Gas/Animal Type	1990	2005	2011	2012	2013	2014	2015

2 Methodology

3 The methodologies presented in IPCC (2006) form the basis of the CH₄ and N₂O emission estimates for each animal
4 type. This section presents a summary of the methodologies used to estimate CH₄ and N₂O emissions from manure
5 management. See Annex 3.11 for more detailed information on the methodology and data used to calculate CH₄ and
6 N₂O emissions from manure management.

7 Methane Calculation Methods

8 The following inputs were used in the calculation of CH₄ emissions:

- 9 • Animal population data (by animal type and state);
- 10 • Typical animal mass (TAM) data (by animal type);
- 11 • Portion of manure managed in each WMS, by state and animal type;
- 12 • Volatile solids (VS) production rate (by animal type and state or United States);
- 13 • Methane producing potential (B₀) of the volatile solids (by animal type); and
- 14 • Methane conversion factors (MCF), the extent to which the CH₄ producing potential is realized for each
15 type of WMS (by state and manure management system, including the impacts of any biogas collection
16 efforts).

17 Methane emissions were estimated by first determining activity data, including animal population, TAM, WMS
18 usage, and waste characteristics. The activity data sources are described below:

- 19 • Annual animal population data for 1990 through 2015 for all livestock types, except goats, horses, mules
20 and asses, and American bison were obtained from the USDA NASS. For cattle, the USDA populations
21 were utilized in conjunction with birth rates, detailed feedlot placement information, and slaughter weight
22 data to create the transition matrix in the CEFM that models cohorts of individual animal types and their
23 specific emission profiles. The key variables tracked for each of the cattle population categories are
24 described in Section 5.1 and in more detail in Annex 3.11. Goat population data for 1992, 1997, 2002,
25 2007, and 2012; horse and mule and ass population data for 1987, 1992, 1997, 2002, 2007, and 2012; and
26 American bison population for 2002, 2007 and 2012 were obtained from the *Census of Agriculture* (USDA
27 2014a). American bison population data for 1990 through 1999 were obtained from the National Bison
28 Association (1999).
- 29 • The TAM is an annual average weight that was obtained for animal types other than cattle from
30 information in USDA's *Agricultural Waste Management Field Handbook* (USDA 1996), the American
31 Society of Agricultural Engineers, Standard D384.1 (ASAE 1998) and others (Meagher 1986; EPA 1992;
32 Safley 2000; ERG 2003b; IPCC 2006; ERG 2010a). For a description of the TAM used for cattle, see
33 Section 5.1.
- 34 • WMS usage was estimated for swine and dairy cattle for different farm size categories using state and
35 regional data from USDA (USDA APHIS 1996; Bush 1998; Ott 2000; USDA 2016d) and EPA (ERG
36 2000a; EPA 2002a and 2002b). For beef cattle and poultry, manure management system usage data were
37 not tied to farm size but were based on other data sources (ERG 2000a; USDA APHIS 2000; UEP 1999).
38 For other animal types, manure management system usage was based on previous estimates (EPA 1992).
39 American bison WMS usage was assumed to be the same as not on feed (NOF) cattle, while mules and
40 asses were assumed to be the same as horses.
- 41 • VS production rates for all cattle except for calves were calculated by head for each state and animal type
42 in the CEFM. VS production rates by animal mass for all other animals were determined using data from
43 USDA's *Agricultural Waste Management Field Handbook* (USDA 1996 and 2008; ERG 2010b and 2010c)
44 and data that was not available in the most recent *Handbook* were obtained from the American Society of
45 Agricultural Engineers, Standard D384.1 (ASAE 1998) or the *2006 IPCC Guidelines* (IPCC 2006).
46 American bison VS production was assumed to be the same as NOF bulls.

- 1 • The maximum CH₄-producing capacity of the VS (B_o) was determined for each animal type based on
2 literature values (Morris 1976; Bryant et al. 1976; Hashimoto 1981; Hashimoto 1984; EPA 1992; Hill
3 1982; Hill 1984).
- 4 • MCFs for dry systems were set equal to default IPCC factors based on state climate for each year (IPCC
5 2006). MCFs for liquid/slurry, anaerobic lagoon, and deep pit systems were calculated based on the
6 forecast performance of biological systems relative to temperature changes as predicted in the van't Hoff-
7 Arrhenius equation which is consistent with IPCC (2006) Tier 2 methodology.
- 8 • Data from anaerobic digestion systems with CH₄ capture and combustion were obtained from the EPA
9 AgSTAR Program, including information presented in the *AgSTAR Digest* (EPA 2000, 2003, 2006) and the
10 AgSTAR project database (EPA 2016). Anaerobic digester emissions were calculated based on estimated
11 methane production and collection and destruction efficiency assumptions (ERG 2008).
- 12 • For all cattle except for calves, the estimated amount of VS (kg per animal-year) managed in each WMS
13 for each animal type, state, and year were taken from the CEFM, assuming American bison VS production
14 to be the same as NOF bulls. For animals other than cattle, the annual amount of VS (kg per year) from
15 manure excreted in each WMS was calculated for each animal type, state, and year. This calculation
16 multiplied the animal population (head) by the VS excretion rate (kg VS per 1,000 kg animal mass per
17 day), the TAM (kg animal mass per head) divided by 1,000, the WMS distribution (percent), and the
18 number of days per year (365.25).

19 The estimated amount of VS managed in each WMS was used to estimate the CH₄ emissions (kg CH₄ per year)
20 from each WMS. The amount of VS (kg per year) were multiplied by the maximum CH₄ producing capacity of the
21 VS (B_o) (m³ CH₄ per kg VS), the MCF for that WMS (percent), and the density of CH₄ (kg CH₄ per m³ CH₄). The
22 CH₄ emissions for each WMS, state, and animal type were summed to determine the total U.S. CH₄ emissions.

23 Nitrous Oxide Calculation Methods

24 The following inputs were used in the calculation of direct and indirect N₂O emissions:

- 25 • Animal population data (by animal type and state);
- 26 • TAM data (by animal type);
- 27 • Portion of manure managed in each WMS (by state and animal type);
- 28 • Total Kjeldahl N excretion rate (N_{ex});
- 29 • Direct N₂O emission factor (EF_{WMS});
- 30 • Indirect N₂O emission factor for volatilization (EF_{volatilization});
- 31 • Indirect N₂O emission factor for runoff and leaching (EF_{runoff/leach});
- 32 • Fraction of N loss from volatilization of NH₃ and NO_x (Frac_{gas}); and
- 33 • Fraction of N loss from runoff and leaching (Frac_{runoff/leach}).

34 Nitrous oxide emissions were estimated by first determining activity data, including animal population, TAM, WMS
35 usage, and waste characteristics. The activity data sources (except for population, TAM, and WMS, which were
36 described above) are described below:

- 37 • Nex rates for all cattle except for calves were calculated by head for each state and animal type in the
38 CEFM. Nex rates by animal mass for all other animals were determined using data from USDA's
39 *Agricultural Waste Management Field Handbook* (USDA 1996 and 2008; ERG 2010b and 2010c) and data
40 from the American Society of Agricultural Engineers, Standard D384.1 (ASAE 1998) and IPCC (2006).
41 American bison Nex rates were assumed to be the same as NOF bulls.⁴
- 42 • All N₂O emission factors (direct and indirect) were taken from IPCC (2006). These data are appropriate
43 because they were developed using U.S. data.

⁴ The N₂O emissions from N excreted (N_{ex}) by American bison on grazing lands are accounted for and discussed in the Agricultural Soil Management source category and included under pasture, range and paddock (PRP) emissions. Because American bison are maintained entirely on unmanaged WMS and N₂O emissions from unmanaged WMS are not included in the Manure Management category, there are no N₂O emissions from American bison included in the Manure Management category.

- Country-specific estimates for the fraction of N loss from volatilization ($Frac_{gas}$) and runoff and leaching ($Frac_{runoff/leach}$) were developed. $Frac_{gas}$ values were based on WMS-specific volatilization values as estimated from EPA's *National Emission Inventory - Ammonia Emissions from Animal Agriculture Operations* (EPA 2005). $Frac_{runoff/leaching}$ values were based on regional cattle runoff data from EPA's Office of Water (EPA 2002b; see Annex 3.11).

To estimate N₂O emissions for cattle (except for calves), the estimated amount of N excreted (kg per animal-year) that is managed in each WMS for each animal type, state, and year were taken from the CEFM. For calves and other animals, the amount of N excreted (kg per year) in manure in each WMS for each animal type, state, and year was calculated. The population (head) for each state and animal was multiplied by TAM (kg animal mass per head) divided by 1,000, the nitrogen excretion rate (N_{ex} , in kg N per 1,000 kg animal mass per day), WMS distribution (percent), and the number of days per year.

Direct N₂O emissions were calculated by multiplying the amount of N excreted (kg per year) in each WMS by the N₂O direct emission factor for that WMS (EF_{WMS} , in kg N₂O-N per kg N) and the conversion factor of N₂O-N to N₂O. These emissions were summed over state, animal, and WMS to determine the total direct N₂O emissions (kg of N₂O per year).

Next, indirect N₂O emissions from volatilization (kg N₂O per year) were calculated by multiplying the amount of N excreted (kg per year) in each WMS by the fraction of N lost through volatilization ($Frac_{tas}$) divided by 100, and the emission factor for volatilization ($EF_{volatilization}$, in kg N₂O per kg N), and the conversion factor of N₂O-N to N₂O. Indirect N₂O emissions from runoff and leaching (kg N₂O per year) were then calculated by multiplying the amount of N excreted (kg per year) in each WMS by the fraction of N lost through runoff and leaching ($Frac_{runoff/leach}$) divided by 100, and the emission factor for runoff and leaching ($EF_{runoff/leach}$, in kg N₂O per kg N), and the conversion factor of N₂O-N to N₂O. The indirect N₂O emissions from volatilization and runoff and leaching were summed to determine the total indirect N₂O emissions.

The direct and indirect N₂O emissions were summed to determine total N₂O emissions (kg N₂O per year).

Uncertainty and Time-Series Consistency

An analysis (ERG 2003a) was conducted for the manure management emission estimates presented in the 1990 through 2001 Inventory report (i.e., 2003 submission to the UNFCCC) to determine the uncertainty associated with estimating CH₄ and N₂O emissions from livestock manure management. The quantitative uncertainty analysis for this source category was performed in 2002 through the IPCC-recommended Approach 2 uncertainty estimation methodology, the Monte Carlo Stochastic Simulation technique. The uncertainty analysis was developed based on the methods used to estimate CH₄ and N₂O emissions from manure management systems. A normal probability distribution was assumed for each source data category. The series of equations used were condensed into a single equation for each animal type and state. The equations for each animal group contained four to five variables around which the uncertainty analysis was performed for each state. These uncertainty estimates were directly applied to the 2015 emission estimates as there have not been significant changes in the methodology since that time.

The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 5-8. Manure management CH₄ emissions in 2015 were estimated to be between 54.3 and 79.5 MMT CO₂ Eq. at a 95 percent confidence level, which indicates a range of 18 percent below to 20 percent above the actual 2015 emission estimate of 66.3 MMT CO₂ Eq. At the 95 percent confidence level, N₂O emissions were estimated to be between 14.9 and 22.0 MMT CO₂ Eq. (or approximately 16 percent below and 24 percent above the actual 2015 emission estimate of 17.7 MMT CO₂ Eq.).

Table 5-8: Approach 2 Quantitative Uncertainty Estimates for CH₄ and N₂O (Direct and Indirect) Emissions from Manure Management (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Manure Management	CH ₄	66.3	54.3	79.5	-18%	20%

Manure Management	N ₂ O	17.7	14.9	22.0	-16%	24%
-------------------	------------------	------	------	------	------	-----

^aRange of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

1 Methodological recalculations were applied to the entire time series to ensure time-series consistency from 1990
 2 through 2015. Details on the emission trends through time are described in more detail in the Methodology section.

3 QA/QC and Verification

4 Tier 1 and Tier 2 QA/QC activities were conducted consistent with the U.S. QA/QC plan. Tier 2 activities focused
 5 on comparing estimates for the previous and current Inventories for N₂O emissions from managed systems and CH₄
 6 emissions from livestock manure. All errors identified were corrected. Order of magnitude checks were also
 7 conducted, and corrections made where needed. Manure N data were checked by comparing state-level data with
 8 bottom up estimates derived at the county level and summed to the state level. Similarly, a comparison was made by
 9 animal and WMS type for the full time series, between national level estimates for N excreted and the sum of county
 10 estimates for the full time series.

11 Any updated data, including population, are validated by experts to ensure the changes are representative of the best
 12 available U.S.-specific data. The U.S.-specific values for TAM, Nex, VS, B_o, and MCF were also compared to the
 13 IPCC default values and validated by experts. Although significant differences exist in some instances, these
 14 differences are due to the use of U.S.-specific data and the differences in U.S. agriculture as compared to other
 15 countries. The U.S. manure management emission estimates use the most reliable country-specific data, which are
 16 more representative of U.S. animals and systems than the IPCC (2006) default values.

17 For additional verification, the implied CH₄ emission factors for manure management (kg of CH₄ per head per year)
 18 were compared against the default IPCC (2006) values. Table 5-9 presents the implied emission factors of kg of CH₄
 19 per head per year used for the manure management emission estimates as well as the IPCC (2006) default emission
 20 factors. The U.S. implied emission factors fall within the range of the IPCC (2006) default values, except in the case
 21 of sheep, goats, and some years for horses and dairy cattle. The U.S. implied emission factors are greater than the
 22 IPCC (2006) default value for those animals due to the use of U.S.-specific data for typical animal mass and VS
 23 excretion. There is an increase in implied emission factors for dairy and swine across the time series. This increase
 24 reflects the dairy and swine industry trend towards larger farm sizes; large farms are more likely to manage manure
 25 as a liquid and therefore produce more CH₄ emissions.

26 **Table 5-9: IPCC (2006) Implied Emission Factor Default Values Compared with Calculated**
 27 **Values for CH₄ from Manure Management (kg/head/year)**
 28

Animal Type	IPCC Default CH ₄ Emission Factors (kg/head/year)	Implied CH ₄ Emission Factors (kg/head/year)						
		1990	2005	2011	2012	2013	2014	2015
Dairy Cattle	48-112	30.2	59.4	70.3	73.9	72.3	73.4	74.0
Beef Cattle	1-2	1.5	1.6	1.7	1.7	1.6	1.6	1.7
Swine	10-45	11.5	15.0	14.5	14.8	14.2	13.8	14.5
Sheep	0.19-0.37	0.6	0.6	0.5	0.5	0.5	0.5	0.5
Goats	0.13-0.26	0.4	0.3	0.3	0.3	0.3	0.3	0.3
Poultry	0.02-1.4	0.1	0.1	0.1	0.1	0.1	0.1	0.1
Horses	1.56-3.13	4.3	3.1	2.6	2.7	2.5	2.5	2.6
American Bison	NA	1.8	2.0	2.1	2.1	2.0	2.0	2.1
Mules and Asses	0.76-1.14	0.9	1.0	1.0	1.0	0.9	0.9	1.0

NA - Not Applicable

29 In addition, default IPCC (2006) emission factors for N₂O were compared to the U.S. Inventory implied N₂O
 30 emission factors. Default N₂O emission factors from the *2006 IPCC Guidelines* were used to estimate N₂O emission
 31 from each WMS in conjunction with U.S.-specific Nex values. The implied emission factors differed from the U.S.
 32 Inventory values due to the use of U.S.-specific Nex values and differences in populations present in each WMS
 33 throughout the time series.

1 Recalculations Discussion

2 The CEFM produces population, VS and Nex data for cattle, excepting calves, that are used in the manure
3 management inventory. As a result, all changes to the CEFM described in Section 5.1 contributed to changes in the
4 population, VS and Nex data used for calculating CH₄ and N₂O cattle emissions from manure management. In
5 addition, the manure management emission estimates included the following recalculations relative to the previous
6 Inventory:

- 7 • State animal populations were updated to reflect updated USDA NASS datasets, which resulted in
8 population changes for:
 - 9 ○ Poultry in 2014;
 - 10 ○ Sheep in 2013;
 - 11 ○ Dairy heifers in 2008 through 2010, and 2014;
 - 12 ○ NOF cattle 2008 through 2010, and 2014;
 - 13 ○ OF cattle for 2008 through 2012, and 2014;
 - 14 ○ Both beef and dairy calves in 2008, 2009, and 2014; and
 - 15 ○ Swine in 2014 (USDA 2016a).
- 16 • WMS distribution data were updated with *Census of Agriculture* farm size distribution data, which resulted
17 in WMS distribution changes for dairy cows and swine for 2008 through 2014, and poultry in 2010 (USDA
18 2016d).
- 19 • Temperature data were updated which resulted in MCF changes for goats, horses, mules, and sheep in
20 2014, as well as dairy cattle, beef cattle, swine and poultry from 2013 through 2014 (NOAA 2016).
- 21 • Anaerobic digester data were updated to reflect updated EPA AgSTAR datasets, which resulted in VS
22 distribution changes for dairy cows, swine, and poultry from 2011 through 2014 (EPA 2016).

23
24 These changes impacted CH₄ emission estimates for 2008 through 2014, overall increasing annual estimations from
25 0.6 to 3.1 percent. Dairy cow methane emissions increased by 1.0 percent in 2008 up to a 5.6 percent increase in
26 2014. Swine increased CH₄ emissions by about 0.2 percent in 2008 up to a 1.0 percent increase in 2013, but
27 decreased CH₄ emissions in 2014 by about 0.7 percent.

28 Planned Improvements

29 The uncertainty analysis for manure management will be updated in future Inventories to more accurately assess
30 uncertainty of emission calculations. This update is necessary due to the extensive changes in emission calculation
31 methodology, including estimation of emissions at the WMS level and the use of new calculations and variables for
32 indirect N₂O emissions.

33 Potential data sources (such as the USDA Agricultural Resource Management Survey) for updated WMS
34 distribution estimates have been reviewed and discussed with USDA. EPA is working with USDA to obtain these
35 data sources for potential use in future Inventory reports. In addition, future Inventory reports may present emissions
36 on a monthly basis to show seasonal emission changes for each WMS; this update would help compare these
37 Inventory data to other data and models.

38 5.3 Rice Cultivation (IPCC Source Category 3C)

39 Most of the world's rice is grown on flooded fields (Baicich 2013), and flooding creates anaerobic conditions that
40 foster CH₄ production through a process known as methanogenesis. Approximately 60 to 90 percent of the CH₄
41 produced by methanogenic bacteria is oxidized in the soil and converted to CO₂ by methanotrophic bacteria. The
42 remainder is emitted to the atmosphere (Holzapfel-Pschorn et al. 1985; Sass et al. 1990) or transported as dissolved
43 CH₄ into groundwater and waterways (Neue et al. 1997). Methane is transported to the atmosphere primarily
44 through the rice plants, but some CH₄ also escapes via ebullition (i.e., bubbling through the water) and to a much
45 lesser extent by diffusion through the water (van Bodegom et al. 2001).

1 Water management is arguably the most important factor affecting CH₄ emissions, and improved water management
 2 has the largest potential to mitigate emissions (Yan et al. 2009). Upland rice fields are not flooded, and therefore do
 3 not produce CH₄, but large amounts of CH₄ can be emitted in continuously irrigated fields, which is the most
 4 common practices in the United States (USDA 2012). Single or multiple aeration events with drainage of a field
 5 during the growing season can significantly reduce these emissions (Wassmann et al. 2000a), but drainage may also
 6 increase N₂O emissions. Deepwater rice fields (i.e., fields with flooding depths greater than one meter, such as
 7 natural wetlands) tend to have less living stems reaching the soil, thus reducing the amount of CH₄ transport to the
 8 atmosphere through the plant compared to shallow-flooded systems (Sass 2001).

9 Other management practices also influence CH₄ emissions from flooded rice fields including rice residue straw
 10 management and application of organic amendments, in addition to cultivar selection due to differences in the
 11 amount of root exudates⁵ among rice varieties (Neue et al. 1997). These practices influence the amount of organic
 12 matter available for methanogenesis, and some practices, such as mulching rice straw or composting organic
 13 amendments, can reduce the amount of labile carbon and limit CH₄ emissions (Wassmann et al. 2000b). Fertilization
 14 practices also influences CH₄ emissions, particularly the use of fertilizers with sulfate (Wassmann et al. 2000b;
 15 Linquist et al. 2012). Other environmental variables also impact the methanogenesis process such as soil
 16 temperature and soil type. Soil temperature is an important factor regulating the activity of methanogenic bacteria
 17 which in turn affects the rate of CH₄ production. Soil texture influences decomposition of soil organic matter, but is
 18 also thought to have an impact on oxidation of CH₄ in the soil (Sass et al. 1994).

19 Rice is currently cultivated in twelve states, including Arkansas, California, Florida, Illinois, Kentucky, Louisiana,
 20 Minnesota, Mississippi, Missouri, New York, South Carolina, Tennessee and Texas. Soil types, rice varieties, and
 21 cultivation practices vary across the United States, but most farmers apply fertilizers and do not harvest crop
 22 residues. In addition, a second, ratoon rice crop is sometimes grown in the Southeast. Ratoon crops are produced
 23 from regrowth of the stubble remaining after the harvest of the first rice crop. Methane emissions from ratoon crops
 24 are higher than those from the primary crops due to the increased amount of labile organic matter available for
 25 anaerobic decomposition in the form of relatively fresh crop residue straw. Emissions tend to be higher in rice fields
 26 if the residues have been in the field for less than 30 days before planting the next rice crop (Lindau and Bollich
 27 1993; IPCC 2006; Wang et al. 2013).

28 Overall, rice cultivation is a minor source of CH₄ emissions in the United States relative to other source categories
 29 (see Table 5-10 and Table 5-11). In 2015, CH₄ emissions from rice cultivation were 11.2 MMT CO₂ Eq. (449 kt).
 30 Annual emissions fluctuate between 1990 and 2015, and emissions in 2015 represented a 30 percent decrease
 31 compared to 1990. Variation in emissions is largely due to differences in the amount of rice harvested areas over
 32 time. In Arkansas rice harvested areas increased by 2 percent from 1990 to 2015, while rice harvested area declined
 33 in California, Louisiana and Texas by 2 percent, 41 percent and 78 percent respectively (see Table 5-12).

34 **Table 5-10: CH₄ Emissions from Rice Cultivation (MMT CO₂ Eq.)**

State	1990	2005	2011	2012	2013	2014	2015
Arkansas	3.3	4.7	4.0	3.8	3.8	3.7	3.8
California	2.0	2.1	1.9	2.0	2.0	2.0	2.0
Florida	+	0.1	+	+	+	+	+
Illinois	+	+	+	+	+	+	+
Kentucky	+	+	+	+	+	+	+
Louisiana	6.1	6.5	5.6	3.9	3.9	4.0	3.8
Minnesota	+	+	+	+	+	+	+
Mississippi	0.6	0.6	0.3	0.5	0.5	0.5	0.5
Missouri	0.3	0.6	0.4	0.3	0.3	0.3	0.3
New York	+	+	+	+	+	+	+
South Carolina	+	+	+	+	+	+	+
Tennessee	+	+	+	+	+	+	+

Total	16.0	16.7	14.1	11.3	11.3	11.4	11.2

⁵ The roots of rice plants add organic material to the soil through a process called “root exudation.” Root exudation is thought to enhance decomposition of the soil organic matter and release nutrients that the plant can absorb and use to stimulate more production. The amount of root exudate produced by a rice plant over a growing season varies among rice varieties.

+ Does not exceed 0.05 MMT CO₂ Eq.
 Note: Totals may not sum due to independent rounding.

 Note: Totals may not sum due to independent rounding.

2 **Figure 5-2: Total Net Annual CH₄ Emissions from Rice Cultivation, 2015 (MMT CO₂ Eq./Year)**
 3 **– TO BE UPDATED FOR FINAL INVENTORY REPORT**

4 Methodology

5 The methodology used to estimate CH₄ emissions from rice cultivation is based on a combination of IPCC Tier 1
 6 and 3 approaches. The Tier 3 method utilizes a process-based model (DAYCENT) to estimate CH₄ emissions from
 7 rice cultivation (Cheng et al. 2013), and has been tested in the United States (See Annex 3.12) and Asia (Cheng et al.
 8 2013, 2014). The model simulates hydrological conditions and thermal regimes, organic matter decomposition, root
 9 exudation, rice plant growth and its influence on oxidation of CH₄, as well as CH₄ transport through the plant and
 10 via ebullition (Cheng et al. 2013). The method simulates the influence of organic amendments and rice straw
 11 management on methanogenesis in the flooded soils. In addition to CH₄ emissions, DAYCENT simulates soil C
 12 stock changes and N₂O emissions (Parton et al. 1987 and 1998; Del Grosso et al. 2010), and allows for a seamless
 13 set of simulations for crop rotations that include both rice and non-rice crops.

14 The Tier 1 method is applied to estimate CH₄ emissions from rice when grown in rotation with crops that are not
 15 simulated by DAYCENT, such as vegetables and perennial/horticultural crops. The Tier 1 method is also used for
 16 areas converted between agriculture (i.e., cropland and grassland) and other land uses, such as forest land, wetland,
 17 and settlements. In addition, the Tier 1 method is used to estimate CH₄ emissions from organic soils (i.e., Histosols)
 18 and from areas with very gravelly, cobbly, or shaley soils (greater than 35 percent by volume). The Tier 3 method
 19 using DAYCENT has not been fully tested for estimating emissions associated with these crops and rotations, land
 20 uses, as well as organic soils or cobbly, gravelly, and shaley mineral soils.

21 The Tier 1 method for estimating CH₄ emissions from rice production utilizes a default base emission rate and
 22 scaling factors (IPCC 2006). The base emission factor represents emissions for continuously flooded fields with no
 23 organic amendments. Scaling factors are used to adjust for water management and organic amendments that differ
 24 from continuous flooding with no organic amendments. The method accounts for pre-season and growing season
 25 flooding; types and amounts of organic amendments; and the number of rice production seasons within a single year
 26 (i.e., single cropping, ratooning, etc.). The Tier 1 analysis is implemented in the Agriculture and Land Use National
 27 Greenhouse Gas Inventory (ALU) software (Ogle et al. 2016).⁶

⁶ See <<http://www.nrel.colostate.edu/projects/ALUsoftware/>>.

1 Rice cultivation areas are based on cropping and land use histories recorded in the USDA National Resources
 2 Inventory (NRI) survey (USDA-NRCS 2015). The NRI is a statistically-based sample of all non-federal land, and
 3 includes 380,956 survey points of which 1,588 are in locations with rice cultivation at the end of the NRI time
 4 series. The Tier 3 method is used to estimate CH₄ emissions from 1,393 of the NRI survey locations, and the
 5 remaining 195 survey locations are estimated with the Tier 1 method. Each NRI survey point is associated with an
 6 “expansion factor” that allows scaling of CH₄ emissions from NRI points to the entire country (i.e., each expansion
 7 factor represents the amount of area with the same land-use/management history as the sample point). Land-use and
 8 some management information in the NRI (e.g., crop type, soil attributes, and irrigation) were collected on a 5-year
 9 cycle beginning in 1982, along with cropping rotation data in 4 out of 5 years for each 5 year time period (i.e., 1979
 10 to 1982, 1984 to 1987, 1989 to 1992, and 1994 to 1997). The NRI program began collecting annual data in 1998,
 11 with data currently available through 2012 (USDA-NRCS 2015). This Inventory only uses NRI data through 2012
 12 because newer data are not available, but will be incorporated when additional years of data are released by USDA-
 13 NRCS. The harvested rice areas in each state are presented in Table 5-12.

14 **Table 5-12: Rice Area Harvested (1,000 Hectares)**

State/Crop	1990	2005	2011	2012	2013	2014	2015
Arkansas	599	796	642	613	613	613	613
California	248	247	249	244	244	244	244
Florida	0	11	0	0	0	0	0
Illinois	0	0	0	0	0	0	0
Kentucky	0	0	0	0	0	0	0
Louisiana	380	402	318	226	226	226	226
Minnesota	4	10	5	6	6	6	6
Mississippi	119	115	53	92	92	92	92
Missouri	47	93	64	46	46	46	46
New York	1	0	0	0	0	0	0
South Carolina	0	0	0	0	0	0	0
Tennessee	0	1	0	0	0	0	0
Texas	300	150	120	66	66	66	66
Total	1,698	1,826	1,451	1,292	1,292	1,292	1,292

Notes: Totals may not sum due to independent rounding. States are included if NRI reports rice areas at any time between 1990 and 2012.

15 The Southeastern states have sufficient growing periods for a ratoon crop in some years. For example, in Arkansas,
 16 the length of growing season is occasionally sufficient for ratoon crops on an average of 1 percent of the rice fields.
 17 No data are available about ratoon crops in Missouri or Mississippi, and the average amount of ratooning in
 18 Arkansas was assigned to these states. Ratoon cropping occurs much more frequently in Louisiana (LSU 2015 for
 19 years 2000 through 2013, 2015) and Texas (TAMU 2015 for years 1993 through 2014), averaging 32 percent and 45
 20 percent of rice acres planted, respectively. Florida also has a large fraction of area with a ratoon crop (49 percent).
 21 Ratoon rice crops are not grown in California. Ratooned crop area as a percent of primary crop area is presented in
 22 Table 5-13.

23 **Table 5-13: Average Ratooned Area as Percent of Primary Growth Area (Percent)**

State	1990-2015
Arkansas ^a	1%
California	0%
Florida ^b	49%
Louisiana ^c	32%
Mississippi ^a	1%
Missouri ^a	0%
Texas ^d	45%

24 ^a Arkansas: 1990–2000 (Slaton 1999 through 2001); 2001–2011 (Wilson 2002 through 2007, 2009 through 2012); 2012–2013
 25 (Hardke 2013, 2014).

26 ^b Florida - Ratoon: 1990–2000 (Schueneman 1997, 1999 through 2001); 2001 (Deren 2002); 2002–2003 (Kirstein 2003 through
 27 2004, 2006); 2004 (Cantens 2004 through 2005); 2005–2013 (Gonzalez 2007 through 2014)

28 ^c Louisiana: 1990–2013 (Linscombe 1999, 2001 through 2014).

^dTexas: 1990–2002 (Klosterboer 1997, 1999 through 2003); 2003–2004 (Stansel 2004 through 2005); 2005 (Texas Agricultural Experiment Station 2006); 2006–2013 (Texas Agricultural Experiment Station 2007 through 2014).

While rice crop production in the United States includes a minor amount of land with mid-season drainage or alternate wet-dry periods, the majority of rice growers use continuously flooded water management systems (Hardke 2015; UCCE 2015; Hollier 1999; Way et al. 2014). Therefore, continuous flooding was assumed in the DAYCENT simulations and the Tier 1 method. Variation in flooding can be incorporated in future Inventories if water management data are collected.

Winter flooding is another key practice associated with water management in rice fields, and the impact of winter flooding on CH₄ emissions is addressed in the Tier 3 and Tier 1 analyses. Flooding is used to prepare fields for the next growing season, and to create waterfowl habitat (Young 2013; Miller et al. 2010; Fleskes et al. 2005). Fitzgerald et al. (2000) suggests that as much as 50 percent of the annual emissions may occur during the winter flood. Winter flooding is a common practice with an average of 34 percent of fields managed with winter flooding in California (Miller et al. 2010; Fleskes et al. 2005), and approximately 21 percent of the fields managed with winter flooding in Arkansas (Wilson and Branson 2005 and 2006; Wilson and Runsick 2007 and 2008; Wilson et al. 2009 and 2010; Hardke and Wilson 2013 and 2014; Hardke 2015). No data are available on winter flooding for Texas, Louisiana, Florida, Missouri, or Mississippi. For these states, the average amount of flooding is assumed to be similar to Arkansas. In addition, the amount of flooding is assumed to be relatively constant over the Inventory time period.

Uncertainty and Time-Series Consistency

Sources of uncertainty in the Tier 3 method include management practices, uncertainties in model structure (i.e., algorithms and parameterization), and variance associated with the NRI sample. Sources of uncertainty in the IPCC (2006) Tier 1 method include the emission factors, management practices, and variance associated with the NRI sample. A Monte Carlo analysis was used to propagate uncertainties in the Tier 1 and 3 methods, and the uncertainties from each approach are combined to produce the final CH₄ emissions estimate using simple error propagation (IPCC 2006). Additional details on the uncertainty methods are provided in Annex 3.12. Rice cultivation CH₄ emissions in 2015 were estimated to be between 8.1 and 14.4 MMT CO₂ Eq. at a 95 percent confidence level, which indicates a range of 28 percent below to 28 percent above the actual 2015 emission estimate of 11.2 MMT CO₂ Eq. (see Table 5-14).

Table 5-14: Approach 2 Quantitative Uncertainty Estimates for CH₄ Emissions from Rice Cultivation (MMT CO₂ Eq. and Percent)

Source	Inventory Method	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
				(MMT CO ₂ Eq.)		(%)	
				Lower Bound	Upper Bound	Lower Bound	Upper Bound
Rice Cultivation	Tier 3	CH ₄	9.9	6.8	13.1	-32%	+32%
Rice Cultivation	Tier 1	CH ₄	1.3	0.9	1.9	-30%	+46%
Rice Cultivation	Total	CH₄	11.2	8.1	14.4	-28%	+28%

^aRange of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section.

QA/QC and Verification

Quality control measures include checking input data, model scripts, and results to ensure data are properly handled throughout the inventory process. Inventory reporting forms and text are reviewed and revised as needed to correct transcription errors. No errors were found in the reporting forms and text.

Model results are compared to field measurements to verify if results adequately represent CH₄ emissions. The comparisons included over 15 long-term experiments, representing about 80 combinations of management

1 treatments across all of the sites. A statistical relationship was developed to assess uncertainties in the model
2 structure and adjust for model bias and assess precision in the resulting estimates (methods are described in Ogle et
3 al. 2007). See Annex 3.12 for more information.

4 Recalculations Discussion

5 Methodological recalculations in the current Inventory are associated with the following improvements: (1)
6 DAYCENT model development to improve the simulation of soil temperature; (2) improvements in the cropping
7 and land use histories that are simulated in DAYCENT between 1950 and 1979, which generate initial values for the
8 state variables in the model and (3) driving the DAYCENT simulations with updated input data for land use and
9 management from the National Resources Inventory, which revised the time series from 1990 through 2012. These
10 changes resulted in an increase in emissions of approximately 25 percent on average relative to the previous
11 Inventory and an increase in uncertainty from confidence interval with a lower bound and upper bound of 17 percent
12 to a confidence interval with an upper and lower bound of 28 percent.

13 Planned Improvements

14 A major improvement is underway to update the time series of management data with information from the USDA-
15 NRCS Conservation Effects Assessment Program (CEAP). This improvement will fill several gaps in the
16 management data including more specific data on fertilizer rates, updated tillage practices, water management,
17 organic amendments and more information on planting and harvesting dates. This improvement is expected to be
18 completed for the 1990 through 2017 Inventory (2019 submission to the UNFCCC). However, the timeline may be
19 extended if there are insufficient resources to fund this improvement.

20 5.4 Agricultural Soil Management (IPCC Source 21 Category 3D)

22 Nitrous oxide is naturally produced in soils through the microbial processes of nitrification and denitrification that is
23 driven by the availability of mineral nitrogen (N) (Firestone and Davidson 1989).⁷ Mineral N is made available in
24 soils through decomposition of soil organic matter and plant litter, as well as asymbiotic fixation of N from the
25 atmosphere.⁸ A number of agricultural activities increase mineral N availability in soils that lead to direct N₂O
26 emissions from nitrification and denitrification at the site of a management activity (see Figure 5-3) (Mosier et al.
27 1998), including N fertilization; application of managed livestock manure and other organic materials such as
28 sewage sludge; deposition of manure on soils by domesticated animals in pastures, rangelands, and paddocks (PRP)
29 (i.e., by grazing animals and other animals whose manure is not managed); production of N-fixing crops and
30 forages; retention of crop residues; and drainage of organic soils (i.e., soils with a high organic matter content,
31 otherwise known as Histosols⁹) (IPCC 2006). Additionally, agricultural soil management activities, including
32 irrigation, drainage, tillage practices, and fallowing of land, can influence N mineralization by impacting moisture
33 and temperature regimes in soils. Indirect emissions of N₂O occur when N is transported from a site and is

⁷ Nitrification and denitrification are driven by the activity of microorganisms in soils. Nitrification is the aerobic microbial oxidation of ammonium (NH₄⁺) to nitrate (NO₃⁻), and denitrification is the anaerobic microbial reduction of nitrate to N₂. Nitrous oxide is a gaseous intermediate product in the reaction sequence of denitrification, which leaks from microbial cells into the soil and then into the atmosphere. Nitrous oxide is also produced during nitrification, although by a less well-understood mechanism (Nevison 2000).

⁸ Asymbiotic N fixation is the fixation of atmospheric N₂ by bacteria living in soils that do not have a direct relationship with plants.

⁹ Drainage of organic soils in former wetlands enhances mineralization of N-rich organic matter, thereby increasing N₂O emissions from these soils.

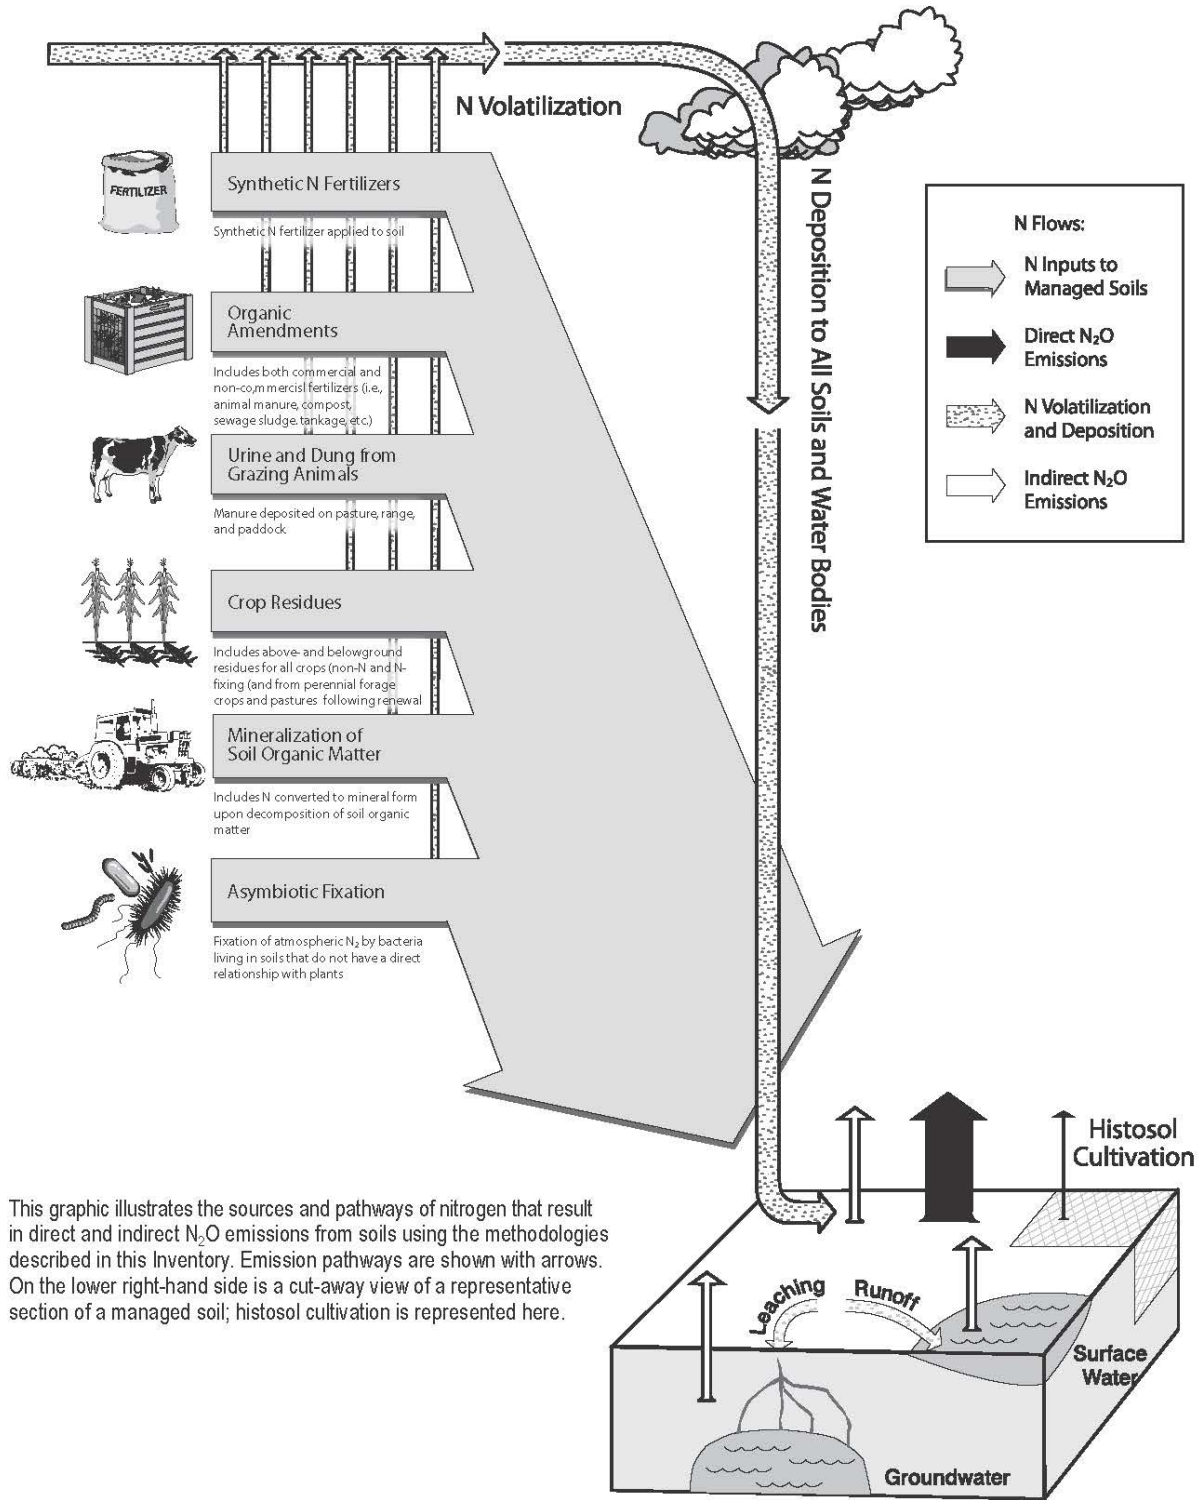

1 subsequently converted to N₂O; there are two pathways for indirect emissions: (1) volatilization and subsequent
2 atmospheric deposition of applied/mineralized N, and (2) surface runoff and leaching of applied/mineralized N into
3 groundwater and surface water.¹⁰

4 Direct and indirect emissions from agricultural lands are included in this section (i.e., cropland and grassland as
5 defined in Section 6.1 Representation of the U.S. Land Base; N₂O emissions from Forest Land and Settlements soils
6 are found in Sections 6.2 and 6.10, respectively). The U.S. Inventory includes all greenhouse gas emissions from
7 managed land based on guidance in IPCC (2006), and consequently N mineralization from decomposition of soil
8 organic matter and asymbiotic N fixation are also included in this section to fully address emissions from the
9 managed land base (see Methodology section for more information).

¹⁰ These processes entail volatilization of applied or mineralized N as NH₃ and NO_x, transformation of these gases within the atmosphere (or upon deposition), and deposition of the N primarily in the form of particulate NH₄⁺, nitric acid (HNO₃), and NO_x, in addition to leaching and runoff of NO₃⁻ that is converted to N₂O in aquatic systems.

1 **Figure 5-3: Sources and Pathways of N that Result in N₂O Emissions from Agricultural Soil Management**
 2

Sources and Pathways of N that Result in N₂O Emissions from Agricultural Soil Management

This graphic illustrates the sources and pathways of nitrogen that result in direct and indirect N₂O emissions from soils using the methodologies described in this Inventory. Emission pathways are shown with arrows. On the lower right-hand side is a cut-away view of a representative section of a managed soil; histosol cultivation is represented here.

1 Agricultural soils produce the majority of N₂O emissions in the United States. Estimated emissions from this source
 2 in 2015 are 251.3 MMT CO₂ Eq. (843 kt) (see Table 5-15 and Table 5-16). Annual N₂O emissions from agricultural
 3 soils fluctuated between 1990 and 2015, although overall emissions are 2.0 percent lower in 2015 than in 1990.
 4 Year-to-year fluctuations are largely a reflection of annual variation in weather patterns, synthetic fertilizer use, and
 5 crop production. From 1990 to 2015, on average cropland accounted for approximately 70 percent of total direct
 6 emissions, while grassland accounted for approximately 30 percent. The percentages for indirect emissions, on
 7 average, are approximately 83 percent of indirect emissions from croplands and 17 percent for grasslands. Estimated
 8 direct and indirect N₂O emissions by sub-source category are shown in Table 5-17 and Table 5-18.

9 **Table 5-15: N₂O Emissions from Agricultural Soils (MMT CO₂ Eq.)**

Activity	1990	2005	2011	2012	2013	2014	2015

Note: Totals may not sum due to independent rounding.

2 Figure 5-4 and Figure 5-5 show regional patterns for direct N₂O emissions for croplands and grasslands, and Figure
 3 5-6 and Figure 5-7 show N losses from volatilization, leaching, and runoff that lead to indirect N₂O emissions.
 4 Annual emissions and N losses in 2015 are shown for the Tier 3 Approach only.

5 **Figure 5-4: Crops, 2015 Annual Direct N₂O Emissions Estimated Using the Tier 3 DAYCENT**
 6 **Model (MMT CO₂ Eq./year)**

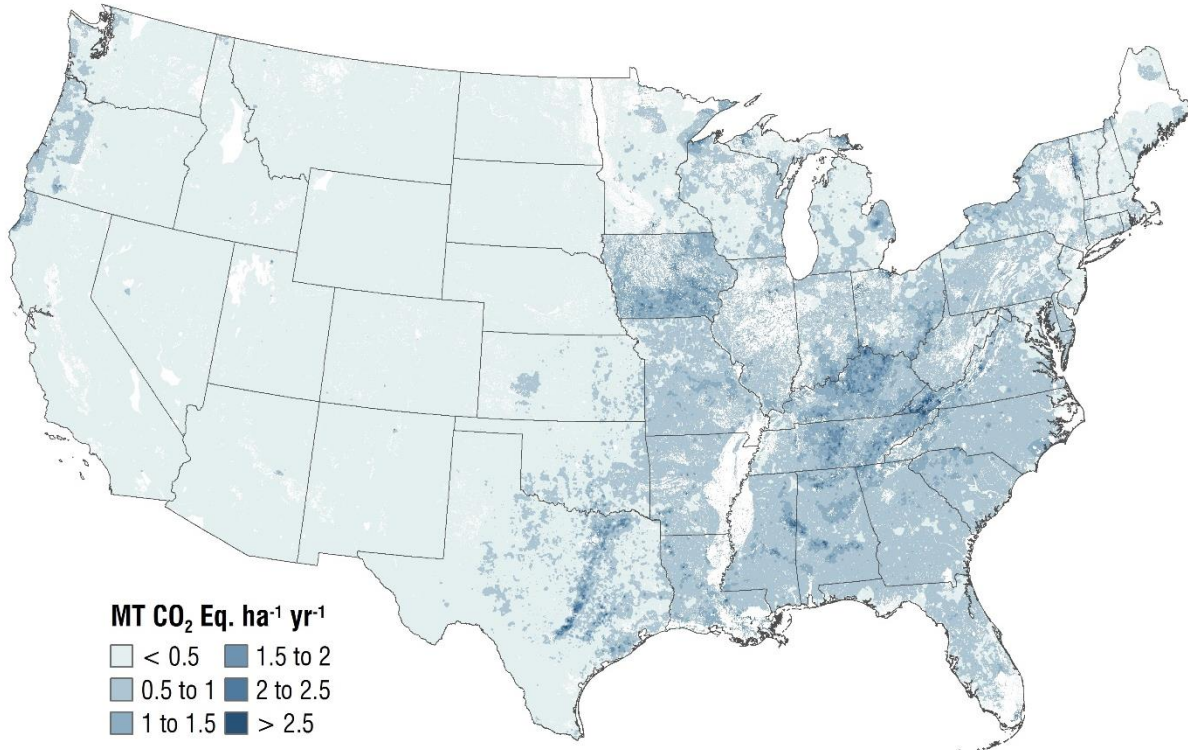

7
 8 Direct N₂O emissions from croplands tend to be high in the Corn Belt (Illinois, Iowa, Indiana, Ohio, southern
 9 Minnesota and Wisconsin, and eastern Nebraska), where a large portion of the land is used for growing highly
 10 fertilized corn and N-fixing soybean crops (see Figure 5-4). Emissions are also high in the Lower Mississippi River
 11 Basin from Missouri to Louisiana, and highly productive irrigated areas, such as Platte River, which flows from
 12 Colorado through Nebraska, Snake River Valley in Idaho and the Central Valley in California. Direct emissions are

1 low in many parts of the eastern United States because only a small portion of land is cultivated as well as in many
 2 western states where rainfall and access to irrigation water are limited.

3 Direct emissions from grasslands are highest in the southeast, particularly Kentucky and Tennessee, in additional to
 4 areas in east Texas and Iowa, where there tends to be higher rates of manure amendments on a relatively small
 5 amount of pasture, compared to other regions of the United States. However, total emissions from grasslands tend to
 6 be higher in the Great Plains and western United States (see Figure 5-5) where a high proportion of the land is used
 7 for cattle grazing.

8 **Figure 5-5: Grasslands, 2015 Annual Direct N₂O Emissions Estimated Using the Tier 3**
 9 **DAYCENT Model (MMT CO₂ Eq./year)**

10

14 **Figure 5-7: Grasslands, 2015 Average Annual N Losses Leading to Indirect N₂O Emissions**
 15 **Estimated Using the Tier 3 DAYCENT Model (kt N/year) – TO BE UPDATED FOR FINAL**
 16 **INVENTORY REPORT**

17 **Methodology**

18 The 2006 IPCC Guidelines (IPCC 2006) divide emissions from the agricultural soil management source category
 19 into five components, including (1) direct emissions from N additions to cropland and grassland mineral soils from
 20 synthetic fertilizers, sewage sludge applications, crop residues, organic amendments, and biological N fixation
 21 associated with planting of legumes on cropland and grassland soils; (2) direct emissions from soil organic matter
 22 mineralization due to land use and management change; (3) direct emissions from drainage of organic soils in
 23 croplands and grasslands; (4) direct emissions from soils due to manure deposited by livestock on PRP grasslands;
 24 and (5) indirect emissions from soils and water from N additions and manure deposition to soils that lead to
 25 volatilization, leaching, or runoff of N and subsequent conversion to N₂O. The United States reports on total

1 emissions from all managed land, which is a proxy for anthropogenic impacts on greenhouse gas emissions (IPCC
2 2006), including direct and indirect N₂O emissions from asymbiotic fixation¹¹ and mineralization of soil organic
3 matter and litter. One recommendation from IPCC (2006) that has not been completely adopted is the estimation of
4 emissions from grassland pasture renewal, which involves occasional plowing to improve forage production in
5 pastures. Currently no data are available to address pasture renewal.

6 **Direct N₂O Emissions**

7 The methodology used to estimate direct N₂O emissions from agricultural soil management in the United States is
8 based on a combination of IPCC Tier 1 and 3 approaches (IPCC 2006; Del Grosso et al. 2010). A Tier 3 process-
9 based model (DAYCENT) is used to estimate direct emissions from a variety of crops that are grown on mineral
10 (i.e., non-organic) soils, as well as the direct emissions from non-federal grasslands with the exception of sewage
11 sludge amendments (Del Grosso et al. 2010). The Tier 3 approach has been specifically designed and tested to
12 estimate N₂O emissions in the United States, accounting for more of the environmental and management influences
13 on soil N₂O emissions than the IPCC Tier 1 method (see Box 5-1 for further elaboration). Moreover, the Tier 3
14 approach allows for the Inventory to address direct N₂O emissions and soil C stock changes from mineral cropland
15 soils in a single analysis. Carbon and N dynamics are linked in plant-soil systems through biogeochemical processes
16 of microbial decomposition and plant production (McGill and Cole 1981). Coupling the two source categories (i.e.,
17 agricultural soil C and N₂O) in a single inventory analysis ensures that there is consistent activity data and treatment
18 of the processes, and interactions are taken into account between C and N cycling in soils.

19 The Tier 3 approach is based on the cropping and land use histories recorded in the USDA National Resources
20 Inventory (NRI) (USDA-NRCS 2015). The NRI is a statistically-based sample of all non-federal land,¹² and
21 includes 363,286 points on agricultural land for the conterminous United States that are included in the Tier 3
22 method. The Tier 1 approach is used to estimate the emissions from the remaining 205,487 in the NRI survey that
23 are designated as cropland or grassland (discussed later in this section). Each point is associated with an “expansion
24 factor” that allows scaling of N₂O emissions from NRI points to the entire country (i.e., each expansion factor
25 represents the amount of area with the same land-use/management history as the sample point). Each NRI point was
26 sampled on a 5-year cycle from 1982 until 1997. For cropland, data were collected in 4 out of 5 years in the cycle
27 (i.e., 1979 through 1982, 1984 through 1987, 1989 through 1992, and 1994 through 1997). In 1998, the NRI
28 program began collecting annual data, and the annual data are currently available through 2012 (USDA-NRCS
29 2015).

30 **Box 5-1: Tier 1 vs. Tier 3 Approach for Estimating N₂O Emissions**

31 The IPCC (2006) Tier 1 approach is based on multiplying activity data on different N inputs (i.e., synthetic fertilizer,
32 manure, N fixation, etc.) by the appropriate default IPCC emission factors to estimate N₂O emissions on an input-
33 by-input basis. The Tier 1 approach requires a minimal amount of activity data, readily available in most countries
34 (e.g., total N applied to crops); calculations are simple; and the methodology is highly transparent. In contrast, the
35 Tier 3 approach developed for this Inventory employs a process-based model (i.e., DAYCENT) that represents the
36 interaction of N inputs, land use and management, as well as environmental conditions at specific locations.
37 Consequently, the Tier 3 approach produces more accurate estimates; it accounts more comprehensively for land-use
38 and management impacts and their interaction with environmental factors (i.e., weather patterns and soil
39 characteristics), which will enhance or dampen anthropogenic influences. However, the Tier 3 approach requires
40 more detailed activity data (e.g., crop-specific N amendment rates), additional data inputs (i.e., daily weather, soil
41 types, etc.), and considerable computational resources and programming expertise. The Tier 3 methodology is less
42 transparent, and thus it is critical to evaluate the output of Tier 3 methods against measured data in order to
43 demonstrate that the method is an improvement over lower tier methods for estimating emissions (IPCC 2006).
44 Another important difference between the Tier 1 and Tier 3 approaches relates to assumptions regarding N cycling.
45 Tier 1 assumes that N added to a system is subject to N₂O emissions only during that year and cannot be stored in

¹¹ N inputs from asymbiotic N fixation are not directly addressed in *2006 IPCC Guidelines*, but are a component of the total emissions from managed lands and are included in the Tier 3 approach developed for this source.

¹² The NRI survey does include sample points on federal lands, but the program does not collect data from those sample locations.

1 soils and contribute to N₂O emissions in subsequent years. This is a simplifying assumption that is likely to create
2 bias in estimated N₂O emissions for a specific year. In contrast, the process-based model used in the Tier 3 approach
3 includes the legacy effect of N added to soils in previous years that is re-mineralized from soil organic matter and
4 emitted as N₂O during subsequent years.

5
6 DAYCENT is used to estimate N₂O emissions associated with production of alfalfa hay, barley, corn, cotton, dry
7 beans, grass hay, grass-clover hay, lentils, oats, onions, peanuts, peas, potatoes, rice, sorghum, soybeans, sugar
8 beets, sunflowers, tobacco, tomatoes, and wheat, but is not applied to estimate N₂O emissions from other crops or
9 rotations with other crops,¹³ such as sugarcane, some vegetables, tobacco, and perennial/horticultural crops. Areas
10 that are converted between agriculture (i.e., cropland and grassland) and other land uses, such as forest land, wetland
11 and settlements, are not simulated with DAYCENT. DAYCENT is also not used to estimate emissions from land
12 areas with very gravelly, cobbly, or shaley soils in the topsoil (greater than 35 percent by volume in the top 30cm of
13 the soil profile), or to estimate emissions from drained organic soils (Histosols). The Tier 3 method has not been
14 fully tested for estimating N₂O emissions associated with these crops and rotations, land uses, as well as organic
15 soils or cobbly, gravelly, and shaley mineral soils. In addition, federal grassland areas are not simulated with
16 DAYCENT due to limited activity on land use histories. For areas that are not included in the DAYCENT
17 simulations, the Tier 1 IPCC (2006) methodology is used to estimate (1) direct emissions from crops on mineral
18 soils that are not simulated by DAYCENT; (2) direct emissions from PRP on federal grasslands; and (3) direct
19 emissions from drained organic soils in croplands and grasslands.

20 *Tier 3 Approach for Mineral Cropland Soils*

21 The DAYCENT biogeochemical model (Parton et al. 1998; Del Grosso et al. 2001 and 2011) is used to estimate
22 direct N₂O emissions from mineral cropland soils that are managed for production of a wide variety of crops (see list
23 in previous paragraph) based on the cropping histories in the 2012 NRI (USDA-NRCS 2015). Crops simulated by
24 DAYCENT are grown on approximately 91 percent of total cropland area in the United States. For agricultural
25 systems in the central region of the United States, crop production for key crops (i.e., corn, soybeans, sorghum,
26 cotton, and wheat) is simulated in DAYCENT with a NASA-CASA production algorithm (Potter et al. 1993; Potter
27 et al. 2007) using the Moderate Resolution Imaging Spectroradiometer (MODIS) Enhanced Vegetation Index (EVI)
28 products, MOD13Q1 and MYD13Q1, with a pixel resolution of 250m.¹⁴

29 DAYCENT is used to estimate direct N₂O emissions due to mineral N available from the following sources: (1) the
30 application of synthetic fertilizers; (2) the application of livestock manure; (3) the retention of crop residues and
31 subsequent mineralization of N during microbial decomposition (i.e., leaving residues in the field after harvest
32 instead of burning or collecting residues); (4) mineralization of soil organic matter; and (5) asymbiotic fixation. Note
33 that commercial organic fertilizers (TVA 1991 through 1994; AAPFCO 1995 through 2016) are addressed with the
34 Tier 1 method because county-level application data would be needed to simulate applications in DAYCENT, and
35 currently data are only available at the national scale. The third and fourth sources are generated internally by the
36 DAYCENT model.

37 Synthetic fertilizer data are based on fertilizer use and rates by crop type for different regions of the United States
38 and are obtained primarily from the USDA Economic Research Service. The data collection program was known as
39 the Cropping Practices Surveys through 1995 (USDA-ERS 1997), and then became the Agricultural Resource
40 Management Surveys (ARMS) (USDA-ERS 2015). Additional data are compiled through other sources particularly
41 the National Agricultural Statistics Service (NASS 1992, 1999, 2004). Frequency and rates of livestock manure
42 application to cropland during 1997 are estimated from data compiled by the USDA Natural Resources
43 Conservation Service (Edmonds et al. 2003), and then adjusted using county-level estimates of manure available for
44 application in other years. The adjustments are based on county-scale ratios of manure available for application to
45 soils in other years relative to 1997 (see Annex 3.12 for further details). Greater availability of managed manure N
46 relative to 1997 is assumed to increase the area amended with manure, while reduced availability of manure N

¹³ A small proportion of the major commodity crop production, such as corn and wheat, is included in the Tier 1 analysis because these crops are rotated with other crops or land uses (e.g., forest lands) that are not simulated by DAYCENT.

¹⁴ See <https://lpdaac.usgs.gov/products/modis_products_table>.

1 relative to 1997 is assumed to reduce the amended area. Data on the county-level N available for application is
2 estimated for managed systems based on the total amount of N excreted in manure minus N losses during storage
3 and transport, and including the addition of N from bedding materials. Nitrogen losses include direct N₂O emissions,
4 volatilization of ammonia and NO_x, runoff and leaching, and poultry manure used as a feed supplement. For
5 unmanaged systems, it is assumed that no N losses or additions occur prior to the application of manure to the soil.
6 More information on livestock manure production is available in Section 5.2: Manure Management and Annex 3.11.

7 The IPCC approach considers crop residue N and N mineralized from soil organic matter as activity data. However,
8 they are not treated as activity data in DAYCENT simulations because residue production, symbiotic N fixation
9 (e.g., legumes), mineralization of N from soil organic matter, and asymbiotic N fixation are internally generated by
10 the model as part of the simulation. In other words, DAYCENT accounts for the influence of symbiotic N fixation,
11 mineralization of N from soil organic matter and crop residue retained in the field, and asymbiotic N fixation on
12 N₂O emissions, but these are not model inputs. The N₂O emissions from crop residues are reduced by approximately
13 3 percent (the assumed average burned portion for crop residues in the U.S.) to avoid double-counting associated
14 with non-CO₂ greenhouse gas emissions from agricultural residue burning. The estimate of residue burning is based
15 on state inventory data (ILENR 1993; Oregon Department of Energy 1995; Noller 1996; Wisconsin Department of
16 Natural Resources 1993; Cibrowski 1996).

17 Additional sources of data are used to supplement the mineral N (USDA-ERS 1997, 2011), livestock manure
18 (Edmonds et al. 2003), and land-use information (USDA-NRCS 2015). The Conservation Technology Information
19 Center (CTIC 2004) provides annual data on tillage activity with adjustments for long-term adoption of no-till
20 agriculture (Towery 2001). Tillage has an influence on soil organic matter decomposition and subsequent soil N₂O
21 emissions. The time series of tillage data from CTIC began in 1989 and ended in 2004, so further changes in tillage
22 practices since 2004 are not currently captured in the Inventory and practices used in 2004 are assumed to apply for
23 subsequent years. Daily weather data are used as an input in the model simulations, based on gridded weather data at
24 a 32 km scale from the North America Regional Reanalysis Product (NARR) (Mesinger et al. 2006). Soil attributes
25 are obtained from the Soil Survey Geographic Database (SSURGO) (Soil Survey Staff 2011).

26 Each NRI point is run 100 times as part of the uncertainty assessment, yielding a total of over 18 million simulations
27 for the analysis. Soil N₂O emission estimates from DAYCENT are adjusted using a structural uncertainty estimator
28 to account for uncertainty in model algorithms and parameter values (Del Grosso et al. 2010). Soil N₂O emissions
29 and associated 95 percent confidence intervals are estimated for each year between 1990 and 2012, but emissions
30 from 2013 to 2015 are assumed to be similar to 2012. Annual data are currently available through 2012 (USDA-
31 NRCS 2015), and the Inventory time series will be updated in the future as new NRI data are released.

32 Nitrous oxide emissions from managed agricultural lands are the result of interactions among anthropogenic
33 activities (e.g., N fertilization, manure application, tillage) and other driving variables, such as weather and soil
34 characteristics. These factors influence key processes associated with N dynamics in the soil profile, including
35 immobilization of N by soil microbial organisms, decomposition of organic matter, plant uptake, leaching, runoff,
36 and volatilization, as well as the processes leading to N₂O production (nitrification and denitrification). It is not
37 possible to partition N₂O emissions into each anthropogenic activity directly from model outputs due to the
38 complexity of the interactions (e.g., N₂O emissions from synthetic fertilizer applications cannot be distinguished
39 from those resulting from manure applications). To approximate emissions by activity, the amount of mineral N
40 added to the soil, or made available through decomposition of soil organic matter and plant litter, as well as
41 asymbiotic fixation of N from the atmosphere, is determined for each N source and then divided by the total amount
42 of mineral N in the soil according to the DAYCENT model simulation. The percentages are then multiplied by the
43 total of direct N₂O emissions in order to approximate the portion attributed to N management practices. This
44 approach is only an approximation because it assumes that all N made available in soil has an equal probability of
45 being released as N₂O, regardless of its source, which is unlikely to be the case (Delgado et al. 2009). However, this
46 approach allows for further disaggregation of emissions by source of N, which is valuable for reporting purposes
47 and is analogous to the reporting associated with the IPCC (2006) Tier 1 method, in that it associates portions of the
48 total soil N₂O emissions with individual sources of N.

49 *Tier 1 Approach for Mineral Cropland Soils*

50 The IPCC (2006) Tier 1 methodology is used to estimate direct N₂O emissions for mineral cropland soils that are not
51 simulated by DAYCENT (e.g., DAYCENT has not been parametrized to simulate all crop types and some soil types
52 such as *Histosols*). For the Tier 1 Approach, estimates of direct N₂O emissions from N applications are based on

1 mineral soil N that is made available from the following practices: (1) the application of synthetic commercial
2 fertilizers; (2) application of managed manure and non-manure commercial organic fertilizers; and (3)
3 decomposition and mineralization of nitrogen from above- and below-ground crop residues in agricultural fields
4 (i.e., crop biomass that is not harvested). Non-manure commercial organic amendments are only included in the Tier
5 1 analysis because these data are not available at the county-level, which is necessary for the DAYCENT
6 simulations.¹⁵ Consequently, all commercial organic fertilizer, as well as manure that is not added to crops in the
7 DAYCENT simulations, are included in the Tier 1 analysis. The following sources are used to derive activity data:

- 8 • A process-of-elimination approach is used to estimate synthetic N fertilizer additions for crop areas not
9 simulated by DAYCENT. The total amount of fertilizer used on farms has been estimated at the county- level
10 by the USGS from sales records (Ruddy et al. 2006), and these data are aggregated to obtain state-level N
11 additions to farms. For 2002 through 2015, state-level fertilizer for on-farm use is adjusted based on annual
12 fluctuations in total U.S. fertilizer sales (AAPFCO 1995 through 2007; AAPFCO 2008 through 2016).¹⁶ After
13 subtracting the portion of fertilizer applied to crops and grasslands simulated by DAYCENT (see Tier 3
14 Approach for Mineral Cropland Soils and Direct N₂O Emissions from Grassland Soils Sections for information
15 on data sources), the remainder of the total fertilizer used on farms is assumed to be applied to crops that are not
16 simulated by DAYCENT.
- 17 • Similarly, a process-of-elimination approach is used to estimate manure N additions for crops that are not
18 simulated by DAYCENT. The amount of manure N applied in the Tier 3 approach to crops and grasslands is
19 subtracted from total manure N available for land application (see Tier 3 Approach for Mineral Cropland Soils
20 and Direct N₂O Emissions from Grassland Soils Sections for information on data sources), and this difference is
21 assumed to be applied to crops that are not simulated by DAYCENT.
- 22 • Commercial organic fertilizer additions are based on organic fertilizer consumption statistics, which are
23 converted to units of N using average organic fertilizer N content (TVA 1991 through 1994, AAPFCO 1995
24 through 2016). Commercial fertilizers do include some manure and sewage sludge, but the amounts are
25 removed from the commercial fertilizer data to avoid double counting with the manure N dataset described
26 above and the sewage sludge amendment data discussed later in this section.
- 27 • Crop residue N is derived by combining amounts of above- and below-ground biomass, which are determined
28 based on NRI crop area data (USDA-NRCS 2013), crop production yield statistics (USDA-NASS 2015), dry
29 matter fractions (IPCC 2006), linear equations to estimate above-ground biomass given dry matter crop yields
30 from harvest (IPCC 2006), ratios of below-to-above-ground biomass (IPCC 2006), and N contents of the
31 residues (IPCC 2006). N inputs from residue were reduced by 3 percent to account for average residue burning
32 portions in the United States.

33 The total increase in soil mineral N from applied fertilizers and crop residues is multiplied by the IPCC (2006)
34 default emission factor to derive an estimate of direct N₂O emissions using the Tier 1 Approach.

35 *Drainage of Organic Soils in Croplands and Grasslands*

36 The IPCC (2006) Tier 1 methods are used to estimate direct N₂O emissions due to drainage of organic soils in
37 croplands or grasslands at a state scale. State-scale estimates of the total area of drained organic soils are obtained
38 from the 2012 NRI (USDA-NRCS 2015) using soils data from the Soil Survey Geographic Database (SSURGO)
39 (Soil Survey Staff 2011). Temperature data from Daly et al. (1994 and 1998) are used to subdivide areas into
40 temperate and tropical climates using the climate classification from IPCC (2006). Annual data are available
41 between 1990 and 2012. Emissions are assumed to be similar to 2012 from 2013 to 2015 because no additional
42 activity data are currently available from the NRI for the latter years. To estimate annual emissions, the total
43 temperate area is multiplied by the IPCC default emission factor for temperate regions, and the total tropical area is
44 multiplied by the IPCC default emission factor for tropical regions (IPCC 2006).

45 *Direct N₂O Emissions from Grassland Soils*

¹⁵ Commercial organic fertilizers include dried blood, tankage, compost, and other, but the dried manure and sewage sludge is removed from the dataset in order to avoid double counting with other datasets that are used for manure N and sewage sludge.

¹⁶ Values are not available for 2014 through 2015 so a “least squares line” statistical extrapolation using the previous 5 years of data is used to arrive at an approximate value for 2014 through 2015.

1 As with N₂O from croplands, the Tier 3 process-based DAYCENT model and Tier 1 method described in IPCC
2 (2006) are combined to estimate emissions from non-federal grasslands and PRP manure N additions for federal
3 grasslands, respectively. Grassland includes pasture and rangeland that produce grass forage primarily for livestock
4 grazing. Rangelands are typically extensive areas of native grassland that are not intensively managed, while
5 pastures are typically seeded grassland (possibly following tree removal) that may also have additional management,
6 such as irrigation, fertilization, or interseeding legumes. DAYCENT is used to simulate N₂O emissions from NRI
7 survey locations (USDA-NRCS 2015) on non-federal grasslands resulting from manure deposited by livestock
8 directly onto pastures and rangelands (i.e., PRP manure), N fixation from legume seeding, managed manure
9 amendments (i.e., manure other than PRP manure such as Daily Spread), and synthetic fertilizer application. Other
10 N inputs are simulated within the DAYCENT framework, including N input from mineralization due to
11 decomposition of soil organic matter and N inputs from senesced grass litter, as well as asymbiotic fixation of N
12 from the atmosphere. The simulations used the same weather, soil, and synthetic N fertilizer data as discussed under
13 the Tier 3 Approach in the Mineral Cropland Soils section. Mineral N fertilization rates are based on Carbon
14 Sequestration Rural Appraisals (CSRA) conducted by the USDA-NRCS (USDA-NRCS, unpublished data). The
15 CSRA was a solicitation of expert knowledge from USDA-NRCS staff throughout the United States to support the
16 national greenhouse gas inventory. Managed manure N amendments to grasslands are estimated from Edmonds et
17 al. (2003) and adjusted for annual variation using data on the availability of managed manure N for application to
18 soils, according to methods described in the Manure Management section (Section 5.2) and Annex 3.11. Biological
19 N fixation is simulated within DAYCENT, and therefore is not an input to the model.

20 Manure N deposition from grazing animals in PRP systems (i.e., PRP manure) is another key input of N to
21 grasslands. The amounts of PRP manure N applied on non-federal grasslands for each NRI point are based on
22 amount of N excreted by livestock in PRP systems. The total amount of N excreted in each county is divided by the
23 grassland area to estimate the N input rate associated with PRP manure. The resulting input rates are used in the
24 DAYCENT simulations. DAYCENT simulations of non-federal grasslands accounted for approximately 78 percent
25 of total PRP manure N in aggregate across the country. The remainder of the PRP manure N in each state is assumed
26 to be excreted on federal grasslands, and the N₂O emissions are estimated using the IPCC (2006) Tier 1 method with
27 IPCC default emission factors. Sewage sludge is assumed to be applied on grasslands because of the heavy metal
28 content and other pollutants in human waste that limit its use as an amendment to croplands. Sewage sludge
29 application is estimated from data compiled by EPA (1993, 1999, 2003), McFarland (2001), and NEBRA (2007).
30 Sewage sludge data on soil amendments to agricultural lands are only available at the national scale, and it is not
31 possible to associate application with specific soil conditions and weather at the county scale. Therefore,
32 DAYCENT could not be used to simulate the influence of sewage sludge amendments on N₂O emissions from
33 grassland soils, and consequently, emissions from sewage sludge are estimated using the IPCC (2006) Tier 1
34 method.

35 Grassland area data are obtained from the U.S. Department of Agriculture NRI (Nusser and Goebel 1997; USDA-
36 NRCS 2015) and the U.S. Geological Survey (USGS) National Land Cover Dataset (Fry et al. 2011; Homer et al.
37 2007; Homer et al. 2015), which are reconciled with the Forest Inventory and Analysis Data. The area data for
38 pastures and rangeland are aggregated to the county level to estimate non-federal and federal grassland areas.

39 N₂O emissions for the PRP manure N deposited on federal grasslands and applied sewage sludge N are estimated
40 using the Tier 1 method by multiplying the N input by the default emission factor. Emissions from manure N are
41 estimated at the state level and aggregated to the entire country, but emissions from sewage sludge N are calculated
42 exclusively at the national scale.

43 As previously mentioned, each NRI point is simulated 100 times as part of the uncertainty assessment, yielding a
44 total of over 18 million simulation runs for the analysis. Soil N₂O emission estimates from DAYCENT are adjusted
45 using a structural uncertainty estimator accounting for uncertainty in model algorithms and parameter values (Del
46 Grosso et al. 2010). Soil N₂O emissions and 95 percent confidence intervals are estimated for each year between
47 1990 and 2012, but emissions from 2013 to 2015 are assumed to be similar to 2012. The annual data are currently
48 available through 2012 (USDA-NRCS 2015) and will be updated when additional data are released.

1 **Total Direct N₂O Emissions from Cropland and Grassland Soils**

2 Annual direct emissions from the Tier 1 and 3 approaches for mineral and drained organic soils occurring in both
3 croplands and grasslands are summed to obtain the total direct N₂O emissions from agricultural soil management
4 (see Table 5-15 and Table 5-16).

5 **Indirect N₂O Emissions**

6 This section describes the methods used for estimating indirect soil N₂O emissions from croplands and grasslands.
7 Indirect N₂O emissions occur when mineral N made available through anthropogenic activity is transported from the
8 soil either in gaseous or aqueous forms and later converted into N₂O. There are two pathways leading to indirect
9 emissions. The first pathway results from volatilization of N as NO_x and NH₃ following application of synthetic
10 fertilizer, organic amendments (e.g., manure, sewage sludge), and deposition of PRP manure. Nitrogen made
11 available from mineralization of soil organic matter and residue, including N incorporated into crops and forage
12 from symbiotic N fixation, and input of N from asymbiotic fixation also contributes to volatilized N emissions.
13 Volatilized N can be returned to soils through atmospheric deposition, and a portion of the deposited N is emitted to
14 the atmosphere as N₂O. The second pathway occurs via leaching and runoff of soil N (primarily in the form of NO₃⁻)
15 that is made available through anthropogenic activity on managed lands, mineralization of soil organic matter and
16 residue, including N incorporated into crops and forage from symbiotic N fixation, and inputs of N into the soil from
17 asymbiotic fixation. The NO₃⁻ is subject to denitrification in water bodies, which leads to N₂O emissions. Regardless
18 of the eventual location of the indirect N₂O emissions, the emissions are assigned to the original source of the N for
19 reporting purposes, which here includes croplands and grasslands.

20 *Indirect N₂O Emissions from Atmospheric Deposition of Volatilized N*

21 The Tier 3 DAYCENT model and IPCC (2006) Tier 1 methods are combined to estimate the amount of N that is
22 volatilized and eventually emitted as N₂O. DAYCENT is used to estimate N volatilization for land areas whose
23 direct emissions are simulated with DAYCENT (i.e., most commodity and some specialty crops and most
24 grasslands). The N inputs included are the same as described for direct N₂O emissions in the Tier 3 Approach for
25 Mineral Cropland Soils and Direct N₂O Emissions from Grassland Soils sections. Nitrogen volatilization from all
26 other areas is estimated using the Tier 1 method and default IPCC fractions for N subject to volatilization (i.e., N
27 inputs on croplands not simulated by DAYCENT, PRP manure N excreted on federal grasslands, sewage sludge
28 application on grasslands). For the volatilization data generated from both the DAYCENT and Tier 1 approaches,
29 the IPCC (2006) default emission factor is used to estimate indirect N₂O emissions occurring due to re-deposition of
30 the volatilized N (see Table 5-18).

31 *Indirect N₂O Emissions from Leaching/Runoff*

32 As with the calculations of indirect emissions from volatilized N, the Tier 3 DAYCENT model and IPCC (2006)
33 Tier 1 method are combined to estimate the amount of N that is subject to leaching and surface runoff into water
34 bodies, and eventually emitted as N₂O. DAYCENT is used to simulate the amount of N transported from lands in
35 the Tier 3 Approach. Nitrogen transport from all other areas is estimated using the Tier 1 method and the IPCC
36 (2006) default factor for the proportion of N subject to leaching and runoff. This N transport estimate includes N
37 applications on croplands that are not simulated by DAYCENT, sewage sludge amendments on grasslands, and PRP
38 manure N excreted on federal grasslands. For both the DAYCENT Tier 3 and IPCC (2006) Tier 1 methods, nitrate
39 leaching is assumed to be an insignificant source of indirect N₂O in cropland and grassland systems in arid regions,
40 as discussed in IPCC (2006). In the United States, the threshold for significant nitrate leaching is based on the
41 potential evapotranspiration (PET) and rainfall amount, similar to IPCC (2006), and is assumed to be negligible in
42 regions where the amount of precipitation plus irrigation does not exceed 80 percent of PET. For leaching and runoff

1 data estimated by the Tier 3 and Tier 1 approaches, the IPCC (2006) default emission factor is used to estimate
 2 indirect N₂O emissions that occur in groundwater and waterways (see Table 5-18).

3 **Uncertainty and Time-Series Consistency**

4 Uncertainty is estimated for each of the following five components of N₂O emissions from agricultural soil
 5 management: (1) direct emissions simulated by DAYCENT; (2) the components of indirect emissions (N volatilized
 6 and leached or runoff) simulated by DAYCENT; (3) direct emissions calculated with the IPCC (2006) Tier 1
 7 method; (4) the components of indirect emissions (N volatilized and leached or runoff) calculated with the IPCC
 8 (2006) Tier 1 method; and (5) indirect emissions estimated with the IPCC (2006) Tier 1 method. Uncertainty in
 9 direct emissions, which account for the majority of N₂O emissions from agricultural management, as well as the
 10 components of indirect emissions calculated by DAYCENT are estimated with a Monte Carlo Analysis, addressing
 11 uncertainties in model inputs and structure (i.e., algorithms and parameterization) (Del Grosso et al. 2010).
 12 Uncertainties in direct emissions calculated with the IPCC (2006) Tier 1 method, the proportion of volatilization and
 13 leaching or runoff estimated with the IPCC (2006) Tier 1 method, and indirect N₂O emissions are estimated with a
 14 simple error propagation approach (IPCC 2006). In addition, uncertainties from the Approach 1 and Approach 3
 15 (i.e., DAYCENT) estimates are combined using simple error propagation (IPCC 2006). Additional details on the
 16 uncertainty methods are provided in Annex 3.12. Table 5-19 shows the combined uncertainty for direct soil N₂O
 17 emissions ranged from 16 percent below to 26 percent above the 2015 emissions estimate of 213.3 MMT CO₂ Eq.,
 18 and the combined uncertainty for indirect soil N₂O emissions range from 46 percent below to 155 percent above the
 19 2015 estimate of 38.0 MMT CO₂ Eq.

20 **Table 5-19: Quantitative Uncertainty Estimates of N₂O Emissions from Agricultural Soil**
 21 **Management in 2015 (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate (MMT CO ₂ Eq.)			
					Lower	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Direct Soil N ₂ O Emissions	N ₂ O	213.3	179.7	267.9	-16%	26%
Indirect Soil N ₂ O Emissions	N ₂ O	38.0	20.5	96.8	-46%	155%

Notes: Due to lack of data, uncertainties in managed manure N production, PRP manure N production, other organic fertilizer amendments, and sewage sludge amendments to soils are currently treated as certain; these sources of uncertainty will be included in future Inventory reports.

22 Additional uncertainty is associated with an incomplete estimation of N₂O emissions from managed croplands and
 23 grasslands in Hawaii and Alaska. The Inventory currently includes the N₂O emissions from mineral fertilizer and
 24 PRP N additions in Alaska and Hawaii, and drained organic soils in Hawaii. Land areas used for agriculture in
 25 Alaska and Hawaii are small relative to major commodity cropping states in the conterminous United States, so the
 26 emissions are likely to be small for the other sources of N (e.g., crop residue inputs), which are not currently
 27 included in the Inventory.

28 Methodological recalculations were applied to the entire time series to ensure time-series consistency from 1990
 29 through 2015. Details on the emission trends through time are described in more detail in the Methodology section.

30 **QA/QC and Verification**

31 DAYCENT results for N₂O emissions and NO₃⁻ leaching are compared with field data representing various cropland
 32 and grassland systems, soil types, and climate patterns (Del Grosso et al. 2005; Del Grosso et al. 2008), and further
 33 evaluated by comparing the model results to emission estimates produced using the IPCC (2006) Tier 1 method for
 34 the same sites. Nitrous oxide measurement data are available for 41 sites, which mostly occur in the United States,
 35 with five in Europe and three in Australia, representing over 200 different combinations of fertilizer treatments and
 36 cultivation practices. Nitrate leaching data are available for four sites in the United States, representing 10 different
 37 combinations of fertilizer amendments/tillage practices. DAYCENT estimates of N₂O emissions are closer to
 38 measured values at most sites compared to the IPCC Tier 1 estimate (see Figure 5-8). In general, the IPCC Tier 1

1 methodology tends to over-estimate emissions when observed values are low and under-estimate emissions when
 2 observed values are high, while DAYCENT estimates have less bias. DAYCENT accounts for key site-level factors
 3 (i.e., weather, soil characteristics, and management) that are not addressed in the IPCC Tier 1 method, and thus the
 4 model is better able to represent the variability in N₂O emissions. DAYCENT does have a tendency to under-
 5 estimate very high N₂O emission rates; and estimates are adjusted using the statistical model derived from the
 6 comparison of model estimates to measurements (see Annex 3.12 for more information). Regardless, the comparison
 7 demonstrates that DAYCENT provides relatively high predictive capability for N₂O emissions, and is an
 8 improvement over the IPCC Tier 1 method.

9 **Figure 5-8: Comparison of Measured Emissions at Field Sites and Modeled Emissions Using**
 10 **the DAYCENT Simulation Model and IPCC Tier 1 Approach (kg N₂O per ha per year)**

11
 12 Spreadsheets containing input data and probability distribution functions required for DAYCENT simulations of
 13 croplands and grasslands and unit conversion factors have been checked, in addition to the program scripts that are
 14 used to run the Monte Carlo uncertainty analysis. Links between spreadsheets have been checked, updated, and
 15 corrected when necessary. Spreadsheets containing input data, emission factors, and calculations required for the
 16 Tier 1 method have been checked and updated as needed.

17 Recalculations Discussion

18 Methodological recalculations in the current Inventory are associated with the following improvements: (1) driving
 19 the DAYCENT simulations with updated input data for land management from the National Resources Inventory
 20 extending the time series through 2012; (2) modifying the number of experimental study sites used to quantify
 21 model uncertainty for direct N₂O emissions; (3) DAYCENT model development to improve the simulation of soil
 22 temperature; (4) improvements in the cropping and land use histories that are simulated in DAYCENT between
 23 1950 and 1979 that generate initial values for the model state variables, such as initial soil organic C stock values;
 24 and (5) implementing a more robust set of model output variables that enabled a more accurate and detailed
 25 accounting of N from synthetic fertilizers, managed manure, and PRP manure applied to grasslands. These changes
 26 resulted in a decrease in emissions of approximately 14.4 percent on average relative to the previous Inventory and
 27 an increase in the upper bound of the 95 percent confidence interval for direct N₂O emissions from 24 to 31 percent.
 28 The differences in emissions and uncertainty are mainly due to modifying the number of study sites used to quantify
 29 model uncertainty.

1 Planned Improvements

2 Several planned improvements are underway. The DAYCENT biogeochemical model will be improved with a better
3 representation of plant phenology, particularly senescence events following grain filling in crops. In addition, crop
4 parameters associated with temperature effects on plant production will be further improved in DAYCENT with
5 additional model calibration. Model development is underway to represent the influence of nitrification inhibitors
6 and slow-release fertilizers (e.g., polymer-coated fertilizers) on N₂O emissions. An improved representation of
7 drainage as well as freeze-thaw cycles are also under development. Experimental study sites will continue to be
8 added for quantifying model structural uncertainty, and studies that have continuous (daily) measurements of N₂O
9 (e.g., Scheer et al. 2013) will be given priority.

10 The time series of management data will be updated with information from the USDA-NRCS Conservation Effects
11 Assessment Program (CEAP). This improvement will fill several gaps in the management data including more
12 specific data on fertilizer rates, updated tillage practices, and more information on planting and harvesting dates for
13 crops.

14 Improvements are underway to simulate crop residue burning in the DAYCENT model based on the amount of crop
15 residues burned according to the data that is used in the Field Burning of Agricultural Residues source category (see
16 Section 5.7).

17 Alaska and Hawaii are not included for all sources in the current Inventory for agricultural soil management, with
18 the exception of N₂O emissions from drained organic soils in croplands and grasslands for Hawaii, synthetic
19 fertilizer and PRP N amendments for grasslands in Alaska and Hawaii. A planned improvement over the next two
20 years is to add the remaining sources for these states into the Inventory analysis.

21 There is also an improvement based on updating the Tier 1 emission factor for N₂O emissions from drained organic
22 soils by using the revised factor in the 2013 Supplement to the 2006 IPCC Guidelines for National Greenhouse Gas
23 Inventories: Wetlands (IPCC 2013).

24 All of these improvements are expected to be completed for the 1990 through 2017 Inventory (2019 submission to
25 the UNFCCC). However, the time line may be extended if there are insufficient resources to fund all or part of these
26 planned improvements.

27 5.5 Liming (IPCC Source Category 3G)

28 Crushed limestone (CaCO₃) and dolomite (CaMg(CO₃)₂) are added to soils by land managers to increase soil pH
29 (i.e., to reduce acidification). Carbon dioxide emissions occur as these compounds react with hydrogen ions in soils.
30 The rate and ultimate magnitude of degradation of applied limestone and dolomite depends on the soil conditions,
31 soil type, climate regime, and whether limestone or dolomite is applied. Emissions from liming of soils have
32 fluctuated over the past 25 years in the United States, ranging from 3.6 MMT CO₂ Eq. to 6.0 MMT CO₂ Eq. In
33 2015, liming of soils in the United States resulted in emissions of 3.8 MMT CO₂ Eq. (1.0 MMT C), representing an
34 18 percent decrease in emissions since 1990 (see Table 5-20 and Table 5-21). The trend is driven by the amount of
35 limestone and dolomite applied to soils over the time period.

36 **Table 5-20: Emissions from Liming (MMT CO₂ Eq.)**

Source	1990	2005	2011	2012	2013	2014	2015
Limestone	4.1	3.9	3.4	4.5	3.6	3.3	3.5
Dolomite	0.6	0.4	0.4	1.5	0.3	0.3	0.3
Total	4.7	4.3	3.9	6.0	3.9	3.6	3.8

Note: Totals may not sum due to independent rounding.

1 **Table 5-21: Emissions from Liming (MMT C)**

Source	1990	2005	2011	2012	2013	2014	2015
Limestone	1.1	1.1	0.9	1.2	1.0	0.9	0.9
Dolomite	0.2	0.1	0.1	0.4	0.1	0.1	0.1
Total	1.3	1.2	1.1	1.6	1.1	1.0	1.0

Note: Totals may not sum due to independent rounding.

2 Methodology

3 Carbon dioxide emissions from application of limestone and dolomite to soils were estimated using a Tier 2
 4 methodology consistent with IPCC (2006). The annual amounts of limestone and dolomite applied (see Table 5-22)
 5 were multiplied by CO₂ emission factors from West and McBride (2005). These emission factors (0.059 metric ton
 6 C/metric ton limestone, 0.064 metric ton C/metric ton dolomite) are lower than the IPCC default emission factors
 7 because they account for the portion of carbonates that are transported from soils through hydrological processes
 8 and eventually deposited in ocean basins (West and McBride 2005). This analysis of lime dissolution is based on
 9 studies in the Mississippi River basin, where the vast majority of lime application occurs in the United States (West
 10 2008). Moreover, much of the remaining lime application is occurring under similar precipitation regimes, and so
 11 the emission factors are considered a reasonable approximation for all lime application in the United States (West
 12 2008).

13 The annual application rates of limestone and dolomite were derived from estimates and industry statistics provided
 14 in the *Minerals Yearbook* and *Mineral Industry Surveys* (Tepordei 1993 through 2006; Willett 2007a, 2007b, 2009,
 15 2010, 2011a, 2011b, 2013a, 2014, 2015 and 2016; USGS 2008 through 2016). The U.S. Geological Survey (USGS;
 16 U.S. Bureau of Mines prior to 1997) compiled production and use information through surveys of crushed stone
 17 manufacturers. However, manufacturers provided different levels of detail in survey responses so the estimates of
 18 total crushed limestone and dolomite production and use were divided into three components: (1) production by end-
 19 use, as reported by manufacturers (i.e., “specified” production); (2) production reported by manufacturers without
 20 end-uses specified (i.e., “unspecified” production); and (3) estimated additional production by manufacturers who
 21 did not respond to the survey (i.e., “estimated” production).

22 Box 5-2: Comparison of the Tier 2 U.S. Inventory Approach and IPCC (2006) Default Approach

23 Emissions from liming of soils were estimated using a Tier 2 methodology based on emission factors specific to the
 24 United States that are lower than the IPCC (2006) emission default factors. Most lime application in the United
 25 States occurs in the Mississippi River basin, or in areas that have similar soil and rainfall regimes as the Mississippi
 26 River basin. Under these conditions, a significant portion of dissolved agricultural lime leaches through the soil into
 27 groundwater. Groundwater moves into channels and is transported to larger rivers and eventually the ocean where
 28 CaCO₃ precipitates to the ocean floor (West and McBride 2005). The U.S.-specific emission factors (0.059 metric
 29 ton C/metric ton limestone and 0.064 metric ton C/metric ton dolomite) are about half of the IPCC (2006) emission
 30 factors (0.12 metric ton C/metric ton limestone and 0.13 metric ton C/metric ton dolomite). For comparison, the
 31 2015 U.S. emission estimate from liming of soils is 3.8 MMT CO₂ Eq. using the U.S.-specific factors. In contrast,
 32 emissions would be estimated at 7.8 MMT CO₂ Eq. using the IPCC (2006) default emission factors.

33
 34 Data on “specified” limestone and dolomite amounts were used directly in the emission calculation because the end
 35 use is provided by the manufacturers and can be used to directly determine the amount applied to soils. However, it
 36 is not possible to determine directly how much of the limestone and dolomite is applied to soils for manufacturer
 37 surveys in the “unspecified” and “estimated” categories. For these categories, the amounts of crushed limestone and
 38 dolomite applied to soils were determined by multiplying the percentage of total “specified” limestone and dolomite
 39 production that is applied to soils, by the total amounts of “unspecified” and “estimated” limestone and dolomite
 40 production. In other words, the proportion of total “unspecified” and “estimated” crushed limestone and dolomite
 41 that was applied to soils is proportional to the amount of total “specified” crushed limestone and dolomite that was
 42 applied to soils.

1 In addition, data were not available for 1990, 1992, and 2015 on the fractions of total crushed stone production that
 2 were limestone and dolomite, and on the fractions of limestone and dolomite production that were applied to soils.
 3 To estimate the 1990 and 1992 data, a set of average fractions were calculated using the 1991 and 1993 data. These
 4 average fractions were applied to the quantity of "total crushed stone produced or used" reported for 1990 and 1992
 5 in the 1994 *Minerals Yearbook* (Tepordei 1996). To estimate 2015 data, 2014 fractions were applied to a 2015
 6 estimate of total crushed stone presented in the USGS *Mineral Industry Surveys: Crushed Stone and Sand and
 7 Gravel in the First Quarter of 2016* (USGS 2016).

8 The primary source for limestone and dolomite activity data is the *Minerals Yearbook*, published by the Bureau of
 9 Mines through 1994 and by the USGS from 1995 to the present. In 1994, the "Crushed Stone" chapter in the
 10 *Minerals Yearbook* began rounding (to the nearest thousand metric tons) quantities for total crushed stone produced
 11 or used. It then reported revised (rounded) quantities for each of the years from 1990 to 1993. In order to minimize
 12 the inconsistencies in the activity data, these revised production numbers have been used in all of the subsequent
 13 calculations.

14 **Table 5-22: Applied Minerals (MMT)**

Mineral	1990	2005	2011	2012	2013	2014	2015
Limestone	19.0	18.1	15.9	20.8	16.4	15.3	16.1
Dolomite	2.4	1.9	1.9	6.3	1.5	1.3	1.4

15 **Uncertainty and Time-Series Consistency**

16 Uncertainty regarding the amount of limestone and dolomite applied to soils was estimated at ±15 percent with
 17 normal densities (Tepordei 2003; Willett 2013b). Analysis of the uncertainty associated with the emission factors
 18 included the fraction of lime dissolved by nitric acid versus the fraction that reacts with carbonic acid, and the
 19 portion of bicarbonate that leaches through the soil and is transported to the ocean. Uncertainty regarding the time
 20 associated with leaching and transport was not addressed in this analysis, but is assumed to be a relatively small
 21 contributor to the overall uncertainty (West 2005). The probability distribution functions for the fraction of lime
 22 dissolved by nitric acid and the portion of bicarbonate that leaches through the soil were represented as smoothed
 23 triangular distributions between ranges of zero and 100 percent of the estimates. The uncertainty surrounding these
 24 two components largely drives the overall uncertainty.

25 A Monte Carlo (Approach 2) uncertainty analysis was applied to estimate the uncertainty in CO₂ emissions from
 26 liming. The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 5-23. Carbon
 27 dioxide emissions from carbonate lime application to soils in 2015 were estimated to be between -0.4 and 7.2 MMT
 28 CO₂ Eq. at the 95 percent confidence level. This confidence interval represents a range of 111 percent below to 88
 29 percent above the 2015 emission estimate of 3.8 MMT CO₂ Eq.

30 **Table 5-23: Approach 2 Quantitative Uncertainty Estimates for CO₂ Emissions from Liming
 31 (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a (MMT CO ₂ Eq.)			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Liming	CO ₂	3.8	(0.4)	7.2	-111%	+88%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

32 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 33 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 34 above.

QA/QC and Verification

A source-specific QA/QC plan for liming has been developed and implemented, and the quality control effort focused on the Tier 1 procedures for this Inventory. No errors were found.

Recalculations Discussion

Adjustments were made in the current Inventory to improve the results. First, limestone and dolomite application data for 2014 were approximated in the previous Inventory using a ratio of total crushed stone for 2014 relative to 2015 (similar to 2015 in the current Inventory). The estimates for 2014 were updated with the recently published data from USGS (2016). With this revision in the activity data, the emissions decreased by 12.8 percent in 2014 relative to the previous Inventory.

5.6 Urea Fertilization (IPCC Source Category 3H)

The use of urea ($\text{CO}(\text{NH}_2)_2$) as a fertilizer leads to CO_2 emissions through the release of CO_2 that was fixed during the industrial production process. In the presence of water and urease enzymes, urea is converted into ammonium (NH_4^+), hydroxyl ion (OH), and bicarbonate (HCO_3^-). The bicarbonate then evolves into CO_2 and water. Emissions from urea fertilization in the United States totaled 5.0 MMT CO_2 Eq. (1.4 MMT C) in 2015 (Table 5-24 and Table 5-25). Due to an increase in application of urea fertilizers between 1990 and 2015, CO_2 emissions have increased by 108 percent from this management activity.

Table 5-24: CO_2 Emissions from Urea Fertilization (MMT CO_2 Eq.)

Source	1990	2005	2011	2012	2013	2014	2015
Urea Fertilization	2.4	3.5	4.1	4.3	4.5	4.8	5.0

Table 5-25: CO_2 Emissions from Urea Fertilization (MMT C)

Source	1990	2005	2011	2012	2013	2014	2015
Urea Fertilization	0.7	1.0	1.1	1.2	1.2	1.3	1.4

Methodology

Carbon dioxide emissions from the application of urea to agricultural soils were estimated using the IPCC (2006) Tier 1 methodology. The method assumes that all CO_2 fixed during the industrial production process of urea are released after application. The annual amounts of urea applied to croplands (see Table 5-26) were derived from the state-level fertilizer sales data provided in *Commercial Fertilizer* reports (TVA 1991, 1992, 1993, 1994; AAPFCO 1995 through 2016). These amounts were multiplied by the default IPCC (2006) emission factor (0.20 metric tons of C per metric ton of urea), which is equal to the C content of urea on an atomic weight basis. Because fertilizer sales data are reported in fertilizer years (July previous year through June current year), a calculation was performed to convert the data to calendar years (January through December). According to monthly fertilizer use data (TVA 1992b), 35 percent of total fertilizer used in any fertilizer year is applied between July and December of the previous calendar year, and 65 percent is applied between January and June of the current calendar year. For example, in the 2000 fertilizer year, 35 percent of the fertilizer was applied in July through December 1999, and 65 percent was applied in January through June 2000.

1 Fertilizer sales data for the 2014 and 2015 fertilizer years (i.e., July 2013 through June 2014 and July 2014 through
 2 June 2015) were not available for this Inventory. Therefore, urea application in the 2014 and 2015 fertilizer years
 3 were estimated using a linear, least squares trend of consumption over the data from the previous five years (2009
 4 through 2013) at the state level. A trend of five years was chosen as opposed to a longer trend as it best captures the
 5 current inter-state and inter-annual variability in consumption. State-level estimates of CO₂ emissions from the
 6 application of urea to agricultural soils were summed to estimate total emissions for the entire United States. The
 7 fertilizer year data is then converted into calendar year data using the method described above.

8 **Table 5-26: Applied Urea (MMT)**

	1990	2005	2011	2012	2013	2014	2015
Urea Fertilizer ^a	3.3	4.8	5.6	5.8	6.1	6.5	6.9

^aThese numbers represent amounts applied to all agricultural land, including *Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, Land Converted to Grassland, Settlements Remaining Settlements, Forest Land Remaining Forest Land* and *Land Converted to Forest Land*, as it is not currently possible to apportion the data by land-use category.

9 Uncertainty and Time-Series Consistency

10 Uncertainty estimates are presented in Table 5-27 for urea fertilization. An Approach 2 Monte Carlo analysis was
 11 completed. The largest source of uncertainty was the default emission factor, which assumes that 100 percent of the
 12 C in CO(NH₂)₂ applied to soils is ultimately emitted into the environment as CO₂. This factor does not incorporate
 13 the possibility that some of the C may be retained in the soil, and therefore the uncertainty range was set from 0
 14 percent emissions to the maximum emission value of 100 percent using a triangular distribution. In addition, urea
 15 consumption data also have uncertainty that is propagated through the emission calculation using a Monte Carlo
 16 simulation approach as described by the IPCC (2006). Carbon dioxide emissions from urea fertilization of
 17 agricultural soils in 2015 were estimated to be between 2.9 and 5.2 MMT CO₂ Eq. at the 95 percent confidence
 18 level. This indicates a range of 43 percent below to 3 percent above the 2015 emission estimate of 5.0 MMT CO₂
 19 Eq.

20 **Table 5-27: Quantitative Uncertainty Estimates for CO₂ Emissions from Urea Fertilization**
 21 **(MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Urea Fertilization	CO ₂	5.0	2.9	5.2	-43%	3%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

23 There are additional uncertainties that are not quantified in this analysis. Urea for non-fertilizer use, such as aircraft
 24 deicing, may be included in consumption totals, but the amount is likely very small. For example, research on
 25 aircraft deicing practices is consistent with this assumption based on a 1992 survey that found a known annual usage
 26 of approximately 2,000 tons of urea for deicing; this would constitute 0.06 percent of the 1992 consumption of urea
 27 (EPA 2000). Similarly, surveys conducted from 2002 to 2005 indicate that total urea use for deicing at U.S. airports
 28 is estimated to be 3,740 metric tons per year, or less than 0.07 percent of the fertilizer total for 2007 (Itle 2009). In
 29 addition, there is uncertainty surrounding the underlying assumptions behind the calculation that converts fertilizer
 30 years to calendar years. These uncertainties are negligible over multiple years, however, because an over- or under-
 31 estimated value in one calendar year is addressed with corresponding increase or decrease in the value for the
 32 subsequent year.

33 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 34 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 35 above.

QA/QC and Verification

A source-specific QA/QC plan for Urea Fertilization has been developed and implemented, and no errors were found.

Recalculations Discussion

Recalculations resulted from updated urea application estimates in a new AAPFCO report (2016). Specifically, the 2012, 2013 and 2014 activity data (i.e., amount of urea applied) for the states of Alabama and Virginia were updated. This resulted in an emissions increase for the United States of 1 percent in 2012, 3.7 percent in 2013 and 5.9 percent in 2014.

5.7 Field Burning of Agricultural Residues (IPCC Source Category 3F)

Crop production creates large quantities of agricultural crop residues, which farmers manage in a variety of ways. For example, crop residues can be left in the field and possibly incorporated into the soil with tillage; collected and used as fuel, animal bedding material, supplemental animal feed, or construction material; composted and applied to soils; transported to landfills; or burned in the field. Field burning of crop residues is not considered a net source of CO₂ emissions because the C released to the atmosphere as CO₂ during burning is reabsorbed during the next growing season by the crop. However, crop residue burning is a net source of CH₄, N₂O, CO, and NO_x, which are released during combustion.

In the United States, field burning of agricultural residues commonly occurs in southeastern states, the Great Plains, and the Pacific Northwest (McCarty 2011). The primary crops that are managed with residue burning include corn, cotton, lentils, rice, soybeans, sugarcane, and wheat (McCarty 2009). Rice, sugarcane, and wheat residues account for approximately 70 percent of all crop residue burning and emissions (McCarty 2011). In 2015, CH₄ and N₂O emissions from field burning of agricultural residues were 0.3 MMT CO₂ Eq. (11 kt) and 0.1 MMT CO₂ Eq. (0.3 kt), respectively (see Table 5-28 and Table 5-29). Annual emissions of CH₄ and N₂O have increased from 1990 to 2015 by 25 percent and 23 percent, respectively. The increase in emissions over time is due to larger amounts of residue production with higher yielding crop varieties and fuel loads.

Table 5-28: CH₄ and N₂O Emissions from Field Burning of Agricultural Residues (MMT CO₂ Eq.)

Gas/Crop Type	1990	2005	2011	2012	2013	2014	2015
CH₄	0.2	0.2	0.3	0.3	0.3	0.3	0.3

+ Does not exceed 0.5 kt.

3 Methodology

4 A U.S.-specific Tier 2 method was used to estimate greenhouse gas emissions from field burning of agricultural
 5 residues (for more details comparing the U.S.-specific approach to the IPCC (2006) default approach, see Box 5-3).
 6 In order to estimate the amounts of C and N released during burning, the following equation was used:

$$7 \text{ C or N released} = \sum \text{ for all crop types and states } \left[\frac{\text{AB}}{\text{CAH} \times \text{CP} \times \text{RCR} \times \text{DMF} \times \text{BE} \times \text{CE} \times (\text{FC or FN})} \right]$$

9 where,

- 11 Area Burned (AB) = Total area of crop burned, by state
- 12 Crop Area Harvested (CAH) = Total area of crop harvested, by state
- 13 Crop Production (CP) = Annual production of crop in kt, by state
- 14 Residue: Crop Ratio (RCR) = Amount of residue produced per unit of crop production
- 15 Dry Matter Fraction (DMF) = Amount of dry matter per unit of biomass for a crop
- 16 Fraction of C or N (FC or FN) = Amount of C or N per unit of dry matter for a crop
- 17 Burning Efficiency (BE) = The proportion of prefire fuel biomass consumed¹⁷
- 18 Combustion Efficiency (CE) = The proportion of C or N released with respect to the total amount of C or N
 19 available in the burned material, respectively

20 Crop Production and Crop Area Harvested were available by state and year from USDA (2016) for all crops (except
 21 rice in Florida and Oklahoma, as detailed below). The amount of C or N released was used in the following equation
 22 to determine the CH₄, CO, N₂O, and NO_x emissions from the Field Burning of Agricultural Residues:

¹⁷ In IPCC/UNEP/OECD/IEA (1997), the equation for C or N released contains the variable 'fraction oxidized in burning'. This variable is equivalent to (burning efficiency × combustion efficiency).

1 CH₄ and CO, or N₂O and NO_x Emissions from Field Burning of Agricultural Residues =
 2 C or N Released × ER × CF

3 where,

- 4 Emissions Ratio (ER) = g CH₄-C or CO-C/g C released, or g N₂O-N or NO_x-N/g N released
 5 Conversion Factor (CF) = conversion, by molecular weight ratio, of CH₄-C to C (16/12), or CO-C to C
 6 (28/12), or N₂O-N to N (44/28), or NO_x-N to N (30/14)
 7

8 **Box 5-3: Comparison of Tier 2 U.S. Inventory Approach and IPCC (2006) Default Approach**

9 Emissions from Field Burning of Agricultural Residues were calculated using a Tier 2 methodology that is based on
 10 the method developed by the IPCC/UNEP/OECD/IEA (1997) and incorporates crop- and country-specific emission
 11 factors and variables. The rationale for using the IPCC/UNEP/OECD/IEA (1997) approach rather than the method
 12 provided in the 2006 IPCC Guidelines is as follows: (1) the equations from both guidelines rely on the same
 13 underlying variables (though the formats differ); (2) the IPCC (2006) equation was developed to be broadly
 14 applicable to all types of biomass burning, and, thus, is not specific to agricultural residues; and (3) the IPCC (2006)
 15 default factors are provided only for four crops (corn, rice, sugarcane, and wheat) while this Inventory includes
 16 emissions from seven crops (corn, cotton, lentils, rice, soybeans, sugarcane, and wheat).

17 A comparison of the methods and factors used in: (1) the current Inventory and (2) the default IPCC (2006)
 18 approach was undertaken in the 1990 through 2015 Inventory report to determine the difference in overall estimates
 19 between the two approaches. To estimate greenhouse gas emissions from field burning of agricultural residues using
 20 the IPCC (2006) methodology, the following equation—cf. IPCC (2006) Equation 2.27—was used:

21
$$\text{Emissions (kt)} = AB \times (M_B \times C_f) \times G_{ef} \times 10^{-6}$$

22 where,

- 23 Area Burned (AB) = Total area of crop burned (ha)
 24 Mass Burned (M_B × C_f) = IPCC (2006) default fuel biomass consumption (metric tons dry matter burnt
 25 ha⁻¹) and US-Specific Values using NASS Statistics (USDA 2016)
 26 Emission Factor (G_{ef}) = IPCC (2006) emission factor (g kg⁻¹ dry matter burnt)

27 The IPCC (2006) Tier 1 method approach that utilizes default mass of fuel values resulted in 1 percent higher
 28 emissions of CH₄ and 14 percent higher emissions of N₂O compared to this Inventory. If U.S.-specific data are used
 29 to derive the Mass of Fuel (M_b) from USDA NASS statistics (USDA 2016), i.e., Tier 2 method, then the IPCC
 30 (2006) method resulted in 28 percent higher emissions of CH₄ and 44 percent higher emissions of N₂O compared to
 31 this Inventory. This larger difference is attributable to lower combustion efficiency values in
 32 IPCC/UNEP/OECD/IEA (1997). In particular, sugarcane has a much lower combustion efficiency value in the
 33 earlier guidelines. A lower value is justified because sugarcane is burned prior to harvesting and has a higher
 34 moisture content that reduces the combustion efficiency, unlike most other crops (IPCC/UNEP/OECD/IEA 1997).
 35 IPCC (2006) does not address the unique burning regime of sugarcane. Overall, the IPCC/UNEP/OECD/IEA (1997)
 36 method is considered more appropriate for U.S. conditions because it is more flexible for incorporating country-
 37 specific data compared to IPCC (2006) approach.

38

39 Crop yield data (except rice in Florida) were based on USDA’s *QuickStats* (USDA 2016), and crop area data were
 40 based on the 2012 NRI (USDA-NRCS 2015). In order to estimate total crop production, the crop yield data from
 41 USDA Quick Stats crop yields was multiplied by the NRI crop areas. Rice yield data for Florida was estimated
 42 separately because yield data were not collected by USDA. Total rice production for Florida was determined using
 43 NRI crop areas and total yields were based on average primary and ratoon rice yields from Schueneman and Deren
 44 (2002). Relative proportions of ratoon crops were derived from information in several publications (Schueneman
 45 1999, 2000, 2001; Deren 2002; Kirstein 2003, 2004; Cantens 2004, 2005; Gonzalez 2007 through 2014). The
 46 production data for the crop types whose residues are burned are presented in Table 5-30. Crop weight by bushel
 47 was obtained from Murphy (1993).

1 The fraction of crop area burned was calculated using data on area burned by crop type and state¹⁸ from McCarty
 2 (2010) for corn, cotton, lentils, rice, soybeans, sugarcane, and wheat.¹⁹ McCarty (2010) used remote sensing data
 3 from MODIS to estimate area burned by crop. State-level area burned data were divided by state-level crop area
 4 harvested data to estimate the percent of crop area burned by crop type for each state. The average percentage of
 5 crop area burned at the national scale is shown in Table 5-31. Data on fraction of crop area burned were only
 6 available from McCarty (2010) for the years 2003 through 2007. For other years in the time series, the percent area
 7 burned was set equal to the average over the five-year period from 2003 to 2007. Table 5-31 shows the resulting
 8 percentage of crop residue burned at the national scale by crop type. State-level estimates are also available upon
 9 request.

10 All residue: crop product mass ratios except sugarcane and cotton were obtained from Strehler and Stützel (1987).
 11 The ratio for sugarcane is from Kinoshita (1988) and the ratio for cotton is from Huang et al. (2007). The residue:
 12 crop ratio for lentils was assumed to be equal to the average of the values for peas and beans. Residue dry matter
 13 fractions for all crops except soybeans, lentils, and cotton were obtained from Turn et al. (1997). Soybean and lentil
 14 dry matter fractions were obtained from Strehler and Stützel (1987); the value for lentil residue was assumed to
 15 equal the value for bean residue. The cotton dry matter fraction was taken from Huang et al. (2007). The residue C
 16 contents and N contents for all crops except soybeans and cotton are from Turn et al. (1997). The residue C content
 17 for soybeans is the IPCC default (IPCC/UNEP/OECD/IEA 1997), and the N content of soybeans is from Barnard
 18 and Kristoferson (1985). The C and N contents of lentils were assumed to equal those of soybeans. The C and N
 19 contents of cotton are from Lachnicht et al. (2004). The burning efficiency was assumed to be 93 percent, and the
 20 combustion efficiency was assumed to be 88 percent, for all crop types, except sugarcane (EPA 1994). For
 21 sugarcane, the burning efficiency was assumed to be 81 percent (Kinoshita 1988) and the combustion efficiency was
 22 assumed to be 68 percent (Turn et al. 1997). See Table 5-32 for a summary of the crop-specific conversion factors.
 23 Emission ratios and mole ratio conversion factors for all gases were based on the *Revised 1996 IPCC Guidelines*
 24 (IPCC/UNEP/OECD/IEA 1997) (see Table 5-33).

25 **Table 5-30: Agricultural Crop Production (kt of Product)**

Crop	1990	2005	2011	2012	2013	2014	2015

Wheat	2%	2%	3%	3%	3%	3%	2%

+ Does not exceed 0.5 percent.

¹⁸ Alaska and Hawaii were excluded.

¹⁹ McCarty (2009) also examined emissions from burning of Kentucky bluegrass and a general “other crops/fallow” category, but USDA crop area and production data were insufficient to estimate emissions from these crops using the methodology employed in the Inventory. McCarty (2009) estimates that approximately 18 percent of crop residue emissions result from burning of the Kentucky bluegrass and “other crops” categories.

1 **Table 5-32: Key Assumptions for Estimating Emissions from Field Burning of Agricultural**
 2 **Residues**

Crop	Residue: Crop	Dry Matter			Burning Efficiency (Fraction)	Combustion Efficiency (Fraction)

NO _x :N	0.121 ^b	30/14

^a Mass of C compound released (units of C) relative to mass of total C released from burning (units of C).

^b Mass of N compound released (units of N) relative to mass of total N released from burning (units of N).

4 Uncertainty and Time-Series Consistency

5 The results of the Approach 2 Monte Carlo uncertainty analysis are summarized in Table 5-34. Methane emissions
 6 from field burning of agricultural residues in 2015 were estimated to be between 0.17 and 0.39 MMT CO₂ Eq. at a
 7 95 percent confidence level. This indicates a range of 40 percent below and 41 percent above the 2015 emission
 8 estimate of 0.3 MMT CO₂ Eq. Nitrous oxide emissions were estimated to be between 0.07 and 0.13 MMT CO₂ Eq.,
 9 or approximately 29 percent below and 30 percent above the 2015 emission estimate of 0.1 MMT CO₂ Eq.

10 **Table 5-34: Approach 2 Quantitative Uncertainty Estimates for CH₄ and N₂O Emissions from**
 11 **Field Burning of Agricultural Residues (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate (MMT CO ₂ Eq.) (%)			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
			Field Burning of Agricultural Residues	CH ₄	0.3	0.17
Field Burning of Agricultural Residues	N ₂ O	0.1	0.07	0.13	-29%	30%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

12 Due to data limitations, there are additional uncertainties in agricultural residue burning, particularly the omission of
 13 burning associated with Kentucky bluegrass and “other crop” residues.

14 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 15 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 16 above.

1 **QA/QC and Verification**

2 A source-specific QA/QC plan for field burning of agricultural residues was implemented with Tier 1 analyses, and
3 no errors were found in this Inventory.

4 **Recalculations Discussion**

5 The crop area data were updated with the 2012 NRI survey (USDA-NRCS 2015). This change resulted in a
6 relatively small change in emissions, with CH₄ and N₂O emissions decreasing by 0.8 percent and 0.5 percent,
7 respectively.

8 **Planned Improvements**

9 A new method is in development that will directly link agricultural residue burning with the Tier 3 methods that are
10 used in several other source categories, including Agricultural Soil Management, *Cropland Remaining Cropland*,
11 and *Land Converted to Cropland* chapters of the Inventory. The method is based on the DAYCENT model, and
12 burning events will be simulated directly within the process-based model framework using information derived from
13 remote sensing fire products. This improvement will lead to greater consistency in the methods for these sources,
14 and better ensure mass balance of C and N in the Inventory analysis.

15

16

6. Land Use, Land-Use Change, and Forestry

This chapter provides an assessment of the greenhouse gas fluxes resulting from land use and conversion of land-use categories in the United States.¹ The Intergovernmental Panel on Climate Change’s *2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2006) recommends reporting fluxes according to changes within and conversions between certain land-use types termed: Forest Land, Cropland, Grassland, Settlements and Wetlands (as well as Other Land).

The greenhouse gas flux from *Forest Land Remaining Forest Land* is reported for all forest ecosystem carbon (C) stocks, harvested wood pools, non-carbon dioxide (non-CO₂) emissions from forest fires, the application of synthetic fertilizers to forest soils, and the draining of organic soils. Fluxes from *Land Converted to Forest Land* are included for C stock changes from mineral soils, aboveground biomass, belowground biomass, dead wood, and litter.

Fluxes are reported for four agricultural land use/land-use change categories: *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, and *Land Converted to Grassland*. The reported greenhouse gas fluxes from these agricultural lands include changes in soil organic C stocks in mineral and organic soils due to land use and management, and for *Forest Land Converted to Cropland* and *Forest Land Converted to Grassland*, the changes in aboveground biomass, belowground biomass, dead wood, and litter C stocks are reported.² The greenhouse gas flux from *Grassland Remaining Grassland* also includes estimates of non-CO₂ emissions from grassland fires.

Fluxes from *Wetlands Remaining Wetlands* include CO₂, methane (CH₄) and nitrous oxide (N₂O) emissions from managed peatlands, as well as C stock changes in coastal wetlands soils, CH₄ emissions from vegetated coastal wetlands, and N₂O emissions from aquaculture in coastal wetlands. Estimates for *Land Converted to Wetlands* include C stock changes and CH₄ emissions from land converted to vegetated coastal wetlands.

Fluxes from *Settlements Remaining Settlements* include those from organic soils, urban trees, application of nitrogen fertilizer to soils, and landfilled yard trimmings and food scraps. The reported greenhouse gas flux from *Land Converted to Settlements* includes changes in organic C stocks in mineral and organic soils due to land use and management, and for *Forest Land Converted to Settlements*, the changes in aboveground biomass, belowground biomass, dead wood, and litter C stocks are also included.

The land use, land-use change, and forestry (LULUCF) sector in 2015 resulted in a net increase in C stocks (i.e., net CO₂ removals) of 386.8 MMT CO₂ Eq. (105.5 MMT C).³ This represents an offset of approximately 5.9 percent of

¹ The term “flux” is used to describe the net emissions of greenhouse gases accounting for both the emissions of CO₂ to and the removals of CO₂ from the atmosphere. Removal of CO₂ from the atmosphere is also referred to as “carbon sequestration.”

² Direct and indirect emissions of N₂O from inputs of N to cropland and grassland soils are included in the Agriculture Chapter.

³ LULUCF C Stock Change is the net C stock change from the following categories: *Forest Land Remaining Forest Land*, *Land Converted to Forest Land*, *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, *Land Converted to Grassland*, *Wetlands Remaining Wetlands*, *Land Converted to Wetlands*, *Settlements Remaining Settlements*, and *Land Converted to Settlements*.

1 total (i.e., gross) greenhouse gas emissions in 2015. Emissions from LULUCF activities in 2015 are 20.4 MMT CO₂
 2 Eq. and represent 0.3 percent of total greenhouse gas emissions.⁴

3 Total C sequestration in the LULUCF sector decreased by approximately 16.0 percent between 1990 and 2015. This
 4 decrease was primarily due to a decrease in the rate of net C accumulation in forests and an increase in emissions
 5 from *Land Converted to Grassland*.⁵ Net C accumulation in *Settlements Remaining Settlements* increased from 1990
 6 to 2015, while net C accumulation in *Forest Land Remaining Forest Land*, *Land Converted to Forest Land*,
 7 *Cropland Remaining Cropland*, and *Grassland Remaining Grassland* slowed over this period. Net C accumulation
 8 remained steady from 1990 to 2015 in *Wetlands Remaining Wetlands* and *Land Converted to Wetlands*. Emissions
 9 from *Land Converted to Cropland* decreased during this period, while emissions from *Land Converted to Grassland*
 10 and *Land Converted to Settlements* increased. The C stock change from LULUCF is summarized in Table 6-1.

11 **Table 6-1: C Stock Change from Land Use, Land-Use Change, and Forestry (MMT CO₂ Eq.)**

Gas/Land-Use Category	1990	2005	2011	2012	2013	2014	2015

LULUCF C Stock Change	(460.7)	(339.3)	(395.8)	(414.5)	(390.3)	(389.2)	(386.8)

+ Absolute value does not exceed 0.05 MMT CO₂ Eq.

^a Includes the effects of net additions to stocks of carbon stored in forest ecosystem pools and harvested wood products.

^b Estimates include C stock changes in all pools.

^c Quality control uncovered errors in the estimate and uncertainty for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, and *Land Converted to Grassland* sections in the LULUCF chapter of this report.

Notes: Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

12 Emissions from LULUCF activities are shown in Table 6-2. Lands undergoing peat extraction (i.e., *Peatlands*
 13 *Remaining Peatlands*) resulted in CO₂ emissions of 0.8 MMT CO₂ Eq. (763 kt of CO₂). Forest fires were the largest
 14 source of CH₄ emissions from LULUCF in 2015, totaling 7.3 MMT CO₂ Eq. (292 kt of CH₄). *Coastal Wetlands*

⁴ LULUCF emissions include the CO₂, CH₄, and N₂O emissions from *Peatlands Remaining Peatlands*; CH₄ and N₂O emissions reported for Non-CO₂ Emissions from Forest Fires, Non-CO₂ Emissions from Grassland Fires, and *Coastal Wetlands Remaining Coastal Wetlands*; CH₄ emissions from *Land Converted to Coastal Wetlands*; and N₂O Fluxes from Forest Soils and Settlement Soils.

⁵ Carbon sequestration estimates are net figures. The C stock in a given pool fluctuates due to both gains and losses. When losses exceed gains, the C stock decreases, and the pool acts as a source. When gains exceed losses, the C stock increases, and the pool acts as a sink; also referred to as net C sequestration or removal.

1 *Remaining Coastal Wetlands* resulted in CH₄ emissions of 3.5 MMT CO₂ Eq. (141 kt of CH₄). Grassland fires
 2 resulted in CH₄ emissions of 0.4 MMT CO₂ Eq. (16 kt of CH₄). *Peatlands Remaining Peatlands* and *Land*
 3 *Converted to Wetlands* resulted in CH₄ emissions of less than 0.05 MMT CO₂ Eq.

4 Forest fires were also the largest source of N₂O emissions from LULUCF in 2015, totaling 4.8 MMT CO₂ Eq. (16 kt
 5 of N₂O). Nitrous oxide emissions from fertilizer application to settlement soils in 2015 totaled to 2.6 MMT CO₂ Eq.
 6 (9 kt of N₂O). This represents an increase of 81.5 percent since 1990. Additionally, the application of synthetic
 7 fertilizers to forest soils in 2015 resulted in N₂O emissions of 0.5 MMT CO₂ Eq. (2 kt of N₂O). Nitrous oxide
 8 emissions from fertilizer application to forest soils have increased by 455 percent since 1990, but still account for a
 9 relatively small portion of overall emissions. Grassland fires resulted in N₂O emissions of 0.4 MMT CO₂ Eq. (1 kt
 10 of N₂O). *Coastal Wetlands Remaining Coastal Wetlands* resulted in N₂O emissions of 0.1 MMT CO₂ Eq. (0.5 kt of
 11 N₂O), and *Peatlands Remaining Peatlands* resulted in N₂O emissions of less than 0.05 MMT CO₂ Eq.

12 Emissions and removals from LULUCF are summarized in Table 6-3 by land-use and category, and Table 6-4 and
 13 Table 6-5 by gas in MMT CO₂ Eq. and kt, respectively.

LULUCF Sector Net Total^g	(449.1)	(315.3)	(375.1)	(387.7)	(370.4)	(368.8)	(366.4)

+ Absolute value does not exceed 0.05 MMT CO₂ Eq.

^a LULUCF C Stock Change is the net C stock change from the following categories: *Forest Land Remaining Forest Land, Land Converted to Forest Land, Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, Land Converted to Grassland, Wetlands Remaining Wetlands, Land Converted to Wetlands, Settlements Remaining Settlements, and Land Converted to Settlements.*

^b Includes the effects of net additions to stocks of carbon stored in forest ecosystem pools and harvested wood products.

^c Quality control uncovered errors in the estimate and uncertainty of soil C stock changes for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, and Land Converted to Grassland* sections in the LULUCF chapter of this report.

^d Estimates include emissions from N fertilizer additions on both *Settlements Remaining Settlements* and *Land Converted to Settlements.*

^e Estimates include emissions from N fertilizer additions on both *Forest Land Remaining Forest Land* and *Land Converted to Forest Land.*

^f LULUCF emissions include the CO₂, CH₄, and N₂O emissions from *Peatlands Remaining Peatlands*; CH₄ and N₂O emissions reported for *Non-CO₂ Emissions from Forest Fires, Non-CO₂ Emissions from Grassland Fires, and Coastal Wetlands Remaining Coastal Wetlands*; CH₄ emissions from *Land Converted to Coastal Wetlands*; and N₂O Fluxes from *Forest Soils and Settlement Soils.*

^g The LULUCF Sector Net Total is the net sum of all emissions (i.e., sources) of greenhouse gases to the atmosphere plus removals of CO₂ (i.e., sinks or negative emissions) from the atmosphere.

Notes: Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

3 **Box 6-1: Methodological Approach for Estimating and Reporting U.S. Emissions and Sinks**

4 In following the UNFCCC requirement under Article 4.1 to develop and submit national greenhouse gas emissions
 5 inventories, the gross emissions total presented in this report for the United States excludes emissions and sinks

1 from LULUCF. The net emissions total presented in this report for the United States includes emissions and sinks
2 from LULUCF. All emissions and sinks estimates are calculated using internationally-accepted methods provided
3 by the IPCC.⁶ Additionally, the calculated emissions and sinks in a given year for the United States are presented in
4 a common manner in line with the UNFCCC reporting guidelines for the reporting of inventories under this
5 international agreement.⁷ The use of consistent methods to calculate emissions and sinks by all nations providing
6 their inventories to the UNFCCC ensures that these reports are comparable. In this regard, U.S. emissions and sinks
7 reported in this Inventory report are comparable to emissions and sinks reported by other countries. The manner that
8 emissions and sinks are provided in this Inventory is one of many ways U.S. emissions and sinks could be
9 examined; this Inventory report presents emissions and sinks in a common format consistent with how countries are
10 to report inventories under the UNFCCC. The report itself follows this standardized format, and provides an
11 explanation of the IPCC methods used to calculate emissions and sinks, and the manner in which those calculations
12 are conducted.

14 6.1 Representation of the U.S. Land Base

15 A national land-use categorization system that is consistent and complete, both temporally and spatially, is needed in
16 order to assess land use and land-use change status and the associated greenhouse gas fluxes over the Inventory time
17 series. This system should be consistent with IPCC (2006), such that all countries reporting on national greenhouse
18 gas fluxes to the UNFCCC should: (1) describe the methods and definitions used to determine areas of managed and
19 unmanaged lands in the country (Table 6-6), (2) describe and apply a consistent set of definitions for land-use
20 categories over the entire national land base and time series (i.e., such that increases in the land areas within
21 particular land-use categories are balanced by decreases in the land areas of other categories unless the national land
22 base is changing) (Table 6-7), and (3) account for greenhouse gas fluxes on all managed lands. The IPCC (2006,
23 Vol. IV, Chapter 1) considers all anthropogenic greenhouse gas emissions and removals associated with land use
24 and management to occur on managed land, and all emissions and removals on managed land should be reported
25 based on this guidance (see IPCC 2010 for further discussion). Consequently, managed land serves as a proxy for
26 anthropogenic emissions and removals. This proxy is intended to provide a practical framework for conducting an
27 inventory, even though some of the greenhouse gas emissions and removals on managed land are influenced by
28 natural processes that may or may not be interacting with the anthropogenic drivers. Guidelines for factoring out
29 natural emissions and removals may be developed in the future, but currently the managed land proxy is considered
30 the most practical approach for conducting an inventory in this sector (IPCC 2010). This section of the Inventory has
31 been developed in order to comply with this guidance.

32 Three databases are used to track land management in the United States and are used as the basis to classify U.S.
33 land area into the thirty-six IPCC land-use and land-use change categories (Table 6-7) (IPCC 2006). The primary
34 databases are the U.S. Department of Agriculture (USDA) National Resources Inventory (NRI)⁸ and the USDA
35 Forest Service (USFS) Forest Inventory and Analysis (FIA)⁹ Database. The Multi-Resolution Land Characteristics
36 Consortium (MRLC) National Land Cover Dataset (NLCD)¹⁰ is also used to identify land uses in regions that were
37 not included in the NRI or FIA.

38 The total land area included in the U.S. Inventory is 936 million hectares across the 50 states.¹¹ Approximately 890
39 million hectares of this land base is considered managed and 46 million hectares is unmanaged, which has not

⁶ See <<http://www.ipcc-nggip.iges.or.jp/public/index.html>>.

⁷ See <<http://unfccc.int/resource/docs/2013/cop19/eng/10a03.pdf>>.

⁸ NRI data are available at <<http://www.nrcs.usda.gov/wps/portal/nrcs/site/national/home>>.

⁹ FIA data are available at <<http://www.fia.fs.fed.us/tools-data/default.asp>>.

¹⁰ NLCD data are available at <<http://www.mrlc.gov/>> and MRLC is a consortium of several U.S. government agencies.

¹¹ The current land representation does not include areas from U.S. Territories, but there are planned improvements to include these regions in future reports.

1 changed by much over the time series of the Inventory (Table 6-7). In 2015, the United States had a total of 293
 2 million hectares of managed Forest Land (2.4 percent increase since 1990), 163 million hectares of Cropland (6.6
 3 percent decrease since 1990), 325 million hectares of managed Grassland (1.1 percent decrease since 1990), 42
 4 million hectares of managed Wetlands (5.6 percent decrease since 1990), 43 million hectares of Settlements (29
 5 percent increase since 1990), and 23 million hectares of managed Other Land (4 percent increase from 1990) (Table
 6 6-7). Wetlands are not differentiated between managed and unmanaged, and are reported solely as managed¹². In
 7 addition, C stock changes are not currently estimated for the entire land base, which leads to discrepancies between
 8 the managed land area data presented here and in the subsequent sections of the Inventory (e.g., *Grassland*
 9 *Remaining Grassland* within interior Alaska).¹³ Planned improvements are under development to account for C
 10 stock changes on all managed land (e.g., Grasslands and Forest Lands in Alaska) and ensure consistency between
 11 the total area of managed land in the land-representation description and the remainder of the Inventory.

12 Dominant land uses vary by region, largely due to climate patterns, soil types, geology, proximity to coastal regions,
 13 and historical settlement patterns (Table 6-6). Forest Land tends to be more common in the eastern states,
 14 mountainous regions of the western United States and Alaska. Cropland is concentrated in the mid-continent region
 15 of the United States, and Grassland is more common in the western United States and Alaska. Wetlands are fairly
 16 ubiquitous throughout the United States, though they are more common in the upper Midwest and eastern portions
 17 of the country. Settlements are more concentrated along the coastal margins and in the eastern states.

20

¹² According to the IPCC (2006), wetlands are considered managed if they are created through human activity, such as dam construction, or the water level is artificially altered by human activity. Distinguishing between managed and unmanaged wetlands in the United States is difficult due to limited data availability. Wetlands are not characterized within the NRI with information regarding water table management. As a result, all Wetlands are reported as managed. See the Planned Improvements section of the Inventory for future refinements to the Wetland area estimates.

¹³ These “managed area” discrepancies also occur in the Common Reporting Format (CRF) tables submitted to the UNFCCC.

^a The abbreviations are “F” for Forest Land, “C” for Cropland, “G” for Grassland, “W” for Wetlands, “S” for Settlements, and “O” for Other Lands. Lands remaining in the same land-use category are identified with the land-use abbreviation given twice (e.g., “FF” is *Forest Land Remaining Forest Land*), and land-use change categories are identified with the previous land use abbreviation followed by the new land-use abbreviation (e.g., “CF” is *Cropland Converted to Forest Land*).

Note: All land areas reported in this table are considered managed. A planned improvement is underway to deal with an exception for Wetlands, which based on the definitions for the current U.S. Land Representation Assessment includes both managed and unmanaged lands. U.S. Territories have not been classified into land uses and are not included in the U.S. Land Representation Assessment. See the Planned Improvements section for discussion on plans to include territories in future inventories. In addition, C stock changes are not currently estimated for the entire land base, which leads to discrepancies between the managed land area data presented here and in the subsequent sections of the Inventory.

 2 **2015**

3

1

2 Methodology

3 IPCC Approaches for Representing Land Areas

4 IPCC (2006) describes three approaches for representing land areas. Approach 1 provides data on the total area for
5 each individual land-use category, but does not provide detailed information on changes of area between categories
6 and is not spatially explicit other than at the national or regional level. With Approach 1, total net conversions
7 between categories can be detected, but not the individual changes (i.e., additions and/or losses) between the land-
8 use categories that led to those net changes. Approach 2 introduces tracking of individual land-use changes between
9 the categories (e.g., Forest Land to Cropland, Cropland to Forest Land, and Grassland to Cropland), using survey
10 samples or other forms of data, but does not provide location data on all parcels of land. Approach 3 extends
11 Approach 2 by providing location data on all parcels of land, such as maps, along with the land-use history. The
12 three approaches are not presented as hierarchical tiers and are not mutually exclusive.

13 According to IPCC (2006), the approach or mix of approaches selected by an inventory agency should reflect
14 calculation needs and national circumstances. For this analysis, the NRI, FIA, and the NLCD have been combined to
15 provide a complete representation of land use for managed lands. These data sources are described in more detail
16 later in this section. NRI and FIA are Approach 2 data sources that do not provide spatially-explicit representations
17 of land use and land-use conversions, even though land use and land-use conversions are tracked explicitly at the
18 survey locations. NRI and FIA data are aggregated and used to develop a land-use conversion matrix for a political
19 or ecologically-defined region. NLCD is a spatially-explicit time series of land-cover data that is used to inform the
20 classification of land use, and is therefore Approach 3 data. Lands are treated as remaining in the same category
21 (e.g., *Cropland Remaining Cropland*) if a land-use change has not occurred in the last 20 years. Otherwise, the land
22 is classified in a land-use change category based on the current use and most recent use before conversion to the
23 current use (e.g., *Cropland Converted to Forest Land*).

24 Definitions of Land Use in the United States

25 *Managed and Unmanaged Land*

26 The United States definition of managed land is similar to the general definition of managed land provided by the
27 IPCC (2006), but with some additional elaboration to reflect national circumstances. Based on the following
28 definitions, most lands in the United States are classified as managed:

- 29 • *Managed Land*: Land is considered managed if direct human intervention has influenced its condition.
30 Direct intervention occurs mostly in areas accessible to human activity and includes altering or maintaining
31 the condition of the land to produce commercial or non-commercial products or services; to serve as
32 transportation corridors or locations for buildings, landfills, or other developed areas for commercial or
33 non-commercial purposes; to extract resources or facilitate acquisition of resources; or to provide social
34 functions for personal, community, or societal objectives where these areas are readily accessible to
35 society.¹⁴
- 36 • *Unmanaged Land*: All other land is considered unmanaged. Unmanaged land is largely comprised of areas
37 inaccessible to society due to the remoteness of the locations. Though these lands may be influenced

¹⁴ Wetlands are an exception to this general definition, because these lands, as specified by IPCC (2006), are only considered managed if they are created through human activity, such as dam construction, or the water level is artificially altered by human activity. Distinguishing between managed and unmanaged wetlands in the United States is difficult due to limited data availability. Wetlands are not characterized within the NRI with information regarding water table management. Therefore, unless wetlands are managed for cropland or grassland, it is not possible to know if they are artificially created or if the water table is managed based on the use of NRI data. As a result, all Wetlands are reported as managed. See the Planned Improvements section of the Inventory for future refinements to the Wetland area estimates.

1 indirectly by human actions such as atmospheric deposition of chemical species produced in industry or
2 CO₂ fertilization, they are not influenced by a direct human intervention.¹⁵

3 In addition, land that is previously managed remains in the managed land base for 20 years before re-classifying the
4 land as unmanaged in order to account for legacy effects of management on C stocks.

5 *Land-Use Categories*

6 As with the definition of managed lands, IPCC (2006) provides general non-prescriptive definitions for the six main
7 land-use categories: Forest Land, Cropland, Grassland, Wetlands, Settlements and Other Land. In order to reflect
8 national circumstances, country-specific definitions have been developed, based predominantly on criteria used in
9 the land-use surveys for the United States. Specifically, the definition of Forest Land is based on the FIA definition
10 of forest,¹⁶ while definitions of Cropland, Grassland, and Settlements are based on the NRI.¹⁷ The definitions for
11 Other Land and Wetlands are based on the IPCC (2006) definitions for these categories.

- 12 • *Forest Land*: A land-use category that includes areas at least 120 feet (36.6 meters) wide and at least one
13 acre (0.4 hectare) in size with at least 10 percent cover (or equivalent stocking) by live trees including land
14 that formerly had such tree cover and that will be naturally or artificially regenerated. Trees are woody
15 plants having a more or less erect perennial stem(s) capable of achieving at least 3 inches (7.6 centimeters)
16 in diameter at breast height, or 5 inches (12.7 cm) diameter at root collar, and a height of 16.4 feet (5 m) at
17 maturity in situ. Forest Land includes all areas recently having such conditions and currently regenerating
18 or capable of attaining such condition in the near future. Forest Land also includes transition zones, such as
19 areas between forest and non-forest lands that have at least 10 percent cover (or equivalent stocking) with
20 live trees and forest areas adjacent to urban and built-up lands. Unimproved roads and trails, streams, and
21 clearings in forest areas are classified as forest if they are less than 120 feet (36.6 m) wide or an acre (0.4
22 ha) in size. However, land is not classified as Forest Land if completely surrounded by urban or developed
23 lands, even if the criteria are consistent with the tree area and cover requirements for Forest Land. These
24 areas are classified as Settlements. In addition, Forest Land does not include land that is predominantly
25 under an agricultural land use (Oswalt et al. 2014).
- 26 • *Cropland*: A land-use category that includes areas used for the production of adapted crops for harvest; this
27 category includes both cultivated and non-cultivated lands. Cultivated crops include row crops or close-
28 grown crops and also hay or pasture in rotation with cultivated crops. Non-cultivated cropland includes
29 continuous hay, perennial crops (e.g., orchards) and horticultural cropland. Cropland also includes land
30 with agroforestry, such as alley cropping and windbreaks,¹⁸ if the dominant use is crop production,
31 assuming the stand or woodlot does not meet the criteria for Forest Land. Lands in temporary fallow or
32 enrolled in conservation reserve programs (i.e., set-asides¹⁹) are also classified as Cropland, as long as
33 these areas do not meet the Forest Land criteria. Roads through Cropland, including interstate highways,
34 state highways, other paved roads, gravel roads, dirt roads, and railroads are excluded from Cropland area
35 estimates and are, instead, classified as Settlements.
- 36 • *Grassland*: A land-use category on which the plant cover is composed principally of grasses, grass-like
37 plants (i.e., sedges and rushes), forbs, or shrubs suitable for grazing and browsing, and includes both
38 pastures and native rangelands. This includes areas where practices such as clearing, burning, chaining,
39 and/or chemicals are applied to maintain the grass vegetation. Grassland may have three or fewer years of

¹⁵ There are some areas, such as Forest Land and Grassland in Alaska that are classified as unmanaged land due to the remoteness of their location.

¹⁶ See <<http://www.fia.fs.fed.us/library/field-guides-methods-proc/docs/2015/Core-FIA-FG-7.pdf>>, page 22.

¹⁷ See <<http://www.nrcs.usda.gov/wps/portal/nrcs/site/national/home>>.

¹⁸ Currently, there is no data source to account for biomass C stock change associated with woody plant growth and losses in alley cropping systems and windbreaks in cropping systems, although these areas are included in the Cropland land base.

¹⁹ A set-aside is cropland that has been taken out of active cropping and converted to some type of vegetative cover, including, for example, native grasses or trees.

1 hay production²⁰ that is otherwise pasture or rangelands. Savannas, deserts, and tundra are considered
2 Grassland.²¹ Drained wetlands are considered Grassland if the dominant vegetation meets the plant cover
3 criteria for Grassland. Woody plant communities of low forbs and shrubs, such as mesquite, chaparral,
4 mountain shrub, and pinyon-juniper, are also classified as Grassland if they do not meet the criteria for
5 Forest Land. Grassland includes land managed with agroforestry practices, such as silvopasture and
6 windbreaks, if the land is principally grasses, grass-like plants, forbs, and shrubs suitable for grazing and
7 browsing, and assuming the stand or woodlot does not meet the criteria for Forest Land. Roads through
8 Grassland, including interstate highways, state highways, other paved roads, gravel roads, dirt roads, and
9 railroads are excluded from Grassland and are, instead, classified as Settlements.

- 10 • *Wetlands*: A land-use category that includes land covered or saturated by water for all or part of the year, in
11 addition to the areas of lakes, reservoirs, and rivers. Managed Wetlands are those where the water level is
12 artificially changed, or were created by human activity. Certain areas that fall under the managed Wetlands
13 definition are included in other land uses based on the IPCC guidance, including Cropland (drained
14 wetlands for crop production and also systems that are flooded for most or just part of the year, such as rice
15 cultivation and cranberry production), Grassland (drained wetlands dominated by grass cover), Forest Land
16 (including drained or un-drained forested wetlands), and Settlements (drained wetlands in developed areas).
- 17 • *Settlements*: A land-use category representing developed areas consisting of units of 0.25 acres (0.1 ha) or
18 more that includes residential, industrial, commercial, and institutional land; construction sites; public
19 administrative sites; railroad yards; cemeteries; airports; golf courses; sanitary landfills; sewage treatment
20 plants; water control structures and spillways; parks within urban and built-up areas; and highways,
21 railroads, and other transportation facilities. Also included are tracts of less than 10 acres (4.05 ha) that may
22 meet the definitions for Forest Land, Cropland, Grassland, or Other Land but are completely surrounded by
23 urban or built-up land, and so are included in the Settlements category. Rural transportation corridors
24 located within other land uses (e.g., Forest Land, Cropland, and Grassland) are also included in
25 Settlements.
- 26 • *Other Land*: A land-use category that includes bare soil, rock, ice, and all land areas that do not fall into
27 any of the other five land-use categories. Following the guidance provided by the IPCC (2006), C stock
28 changes and non-CO₂ emissions are not estimated for Other Lands because these areas are largely devoid of
29 biomass, litter and soil C pools. However, C stock changes and non-CO₂ emissions are estimated for *Land*
30 *Converted to Other Land* during the first 20 years following conversion to account for legacy effects.

31 Land-Use Data Sources: Description and Application to U.S. 32 Land Area Classification

33 U.S. Land-Use Data Sources

34 The three main sources for land-use data in the United States are the NRI, FIA, and the NLCD (Table 6-8). These
35 data sources are combined to account for land use in all 50 states. FIA and NRI data are used when available for an
36 area because the surveys contain additional information on management, site conditions, crop types, biometric
37 measurements, and other data that is needed to estimate C stock changes, N₂O, and CH₄ emissions on those lands. If
38 NRI and FIA data are not available for an area, however, then the NLCD product is used to represent the land use.

²⁰ Areas with four or more years of continuous hay production are Cropland because the land is typically more intensively managed with cultivation, greater amounts of inputs, and other practices.

²¹ 2006 IPCC Guidelines do not include provisions to separate desert and tundra as land-use categories.

National Resources Inventory

For the Inventory, the NRI is the official source of data for land use and land use change on non-federal lands in the conterminous United States and Hawaii (except Forest Land), and is also used to determine the total land base for the conterminous United States and Hawaii. The NRI is a statistically-based survey conducted by the USDA Natural Resources Conservation Service and is designed to assess soil, water, and related environmental resources on non-federal lands. The NRI has a stratified multi-stage sampling design, where primary sample units are stratified on the basis of county and township boundaries defined by the United States Public Land Survey (Nusser and Goebel 1997). Within a primary sample unit (typically a 160 acre [64.75 ha] square quarter-section), three sample points are selected according to a restricted randomization procedure. Each point in the survey is assigned an area weight (expansion factor) based on other known areas and land-use information (Nusser and Goebel 1997). The NRI survey utilizes data derived from remote sensing imagery and site visits in order to provide detailed information on land use and management, particularly for Croplands and Grasslands (i.e., agricultural lands), and is used as the basis to account for C stock changes in agricultural lands (except federal Grasslands). The NRI survey was conducted every 5 years between 1982 and 1997, but shifted to annualized data collection in 1998. The land use between five-year periods from 1982 and 1997 are assumed to be the same for a five-year time period if the land use is the same at the beginning and end of the five-year period (Note: most of the data has the same land use at the beginning and end of the five-year periods). If the land use had changed during a five-year period, then the change is assigned at random to one of the five years. For crop histories, years with missing data are estimated based on the sequence of crops grown during years preceding and succeeding a missing year in the NRI history. This gap-filling approach allows for development of a full time series of land-use data for non-federal lands in the conterminous United States and Hawaii. This Inventory incorporates data through 2012 from the NRI. The land use patterns are assumed to remain the same from 2012 through 2015 for this Inventory, but the time series will be updated when new data are released.

Forest Inventory and Analysis

The FIA program, conducted by the USFS, is another statistically-based survey for the conterminous United States, and the official source of data on Forest Land area and management data for the Inventory. FIA engages in a hierarchical system of sampling, with sampling categorized as Phases 1 through 3, in which sample points for phases are subsets of the previous phase. Phase 1 refers to collection of remotely-sensed data (either aerial photographs or

1 satellite imagery) primarily to classify land into forest or non-forest and to identify landscape patterns like
2 fragmentation and urbanization. Phase 2 is the collection of field data on a network of ground plots that enable
3 classification and summarization of area, tree, and other attributes associated with forest-land uses. Phase 3 plots are
4 a subset of Phase 2 plots where data on indicators of forest health are measured. Data from all three phases are also
5 used to estimate C stock changes for Forest Land. Historically, FIA inventory surveys have been conducted
6 periodically, with all plots in a state being measured at a frequency of every five to 14 years. A new national plot
7 design and annual sampling design was introduced by FIA about ten years ago. Most states, though, have only
8 recently been brought into this system. Annualized sampling means that a portion of plots throughout each state is
9 sampled each year, with the goal of measuring all plots once every five years. See Annex 3.13 to see the specific
10 survey data available by state. The most recent year of available data varies state by state (range of most recent data
11 is from 2012 through 2015; see Table A-255).

12 *National Land Cover Dataset*

13 While the NRI survey sample covers the conterminous United States and Hawaii, land use data are only collected on
14 non-federal lands. In addition, FIA only records data for forest land across the land base in the conterminous United
15 States and a portion of Alaska.²² Consequently, gaps exist in the land representation when the datasets are
16 combined, such as federal grassland operated by Bureau of Land Management (BLM), USDA, and National Park
17 Service, as well as Alaska.²³ The NLCD is used as a supplementary database to account for land use on federal
18 lands in the conterminous United States and Hawaii, in addition to federal and non-federal lands in Alaska.

19 NLCD products provide land-cover for 1992, 2001, 2006, and 2011 in the conterminous United States (Homer et al.
20 2007), and also for Alaska in 2001 and 2011 and Hawaii in 2001. For the conterminous United States, the NLCD
21 data have been further processed to derive Land Cover Change Products for 2001, 2006, and 2011 (Fry et al. 2011;
22 Homer et al. 2007; Homer et al. 2015). A Land Cover Change Product is also available for Alaska from 2001 to
23 2011. A NLCD change product is not available for Hawaii because data are only available for one year, i.e., 2001.
24 The NLCD products are based primarily on Landsat Thematic Mapper imagery at a 30 meter resolution, and contain
25 21 categories of land-cover information, which have been aggregated into the 36 IPCC land-use categories for the
26 conterminous United States and Alaska, and into the six IPCC land-use categories for Hawaii.

27 The aggregated maps of IPCC land-use categories were used in combination with the NRI database to represent land
28 use and land-use change for federal lands, as well as federal and non-federal lands in Alaska. Specifically, NRI
29 survey locations designated as federal lands were assigned a land use/land use change category based on the NLCD
30 maps that had been aggregated into the IPCC categories. This analysis addressed shifts in land ownership across
31 years between federal or non-federal classes as represented in the NRI survey (i.e., the ownership is classified for
32 each survey location in the NRI). The sources of these additional data are discussed in subsequent sections of the
33 NIR.

34 **Managed Land Designation**

35 Lands are designated as managed in the United States based on the definition provided earlier in this section. In
36 order to apply the definition in an analysis of managed land, the following criteria are used:

- 37 • All Croplands and Settlements are designated as managed so only Grassland, Forest Land or Other
38 Lands may be designated as unmanaged land;
- 39 • All Forest Lands with active fire protection are considered managed;
- 40 • All Grassland is considered managed at a county scale if there are livestock in the county;²⁴
- 41 • Other areas are considered managed if accessible based on the proximity to roads and other
42 transportation corridors, and/or infrastructure;

²² FIA does collect some data on non-forest land use, but these are held in regional databases versus the national database. The status of these data is being investigated.

²³ The FIA and NRI survey programs also do not include U.S. Territories with the exception of non-federal lands in Puerto Rico, which are included in the NRI survey. Furthermore, NLCD does not include coverage for all U.S. Territories.

²⁴ Assuming all Grasslands are grazed in a county with even very small livestock populations is a conservative assumption about human impacts on Grasslands. Currently, detailed information on grazing at sub-county scales is not available for the United States to make a finer delineation of managed land.

- 1 • Protected lands maintained for recreational and conservation purposes are considered managed (i.e.,
- 2 managed by public and private organizations);
- 3 • Lands with active and/or past resource extraction are considered managed; and
- 4 • Lands that were previously managed but subsequently classified as unmanaged, remain in the managed
- 5 land base for 20 years following the conversion to account for legacy effects of management on C
- 6 stocks.

7 The analysis of managed lands is conducted using a geographic information system. Lands that are used for crop
8 production or settlements are determined from the NLCD (Fry et al. 2011; Homer et al. 2007; Homer et al. 2015).
9 Forest Lands with active fire management are determined from maps of federal and state management plans from
10 the National Atlas (U.S. Department of Interior 2005) and Alaska Interagency Fire Management Council (1998). It
11 is noteworthy that all forest lands in the conterminous United States have active fire protection, and are therefore
12 designated as managed regardless of accessibility or other criteria. The designation of grasslands as managed is
13 based on livestock population data at the county scale from the USDA National Agricultural Statistics Service (U.S.
14 Department of Agriculture 2015). Accessibility is evaluated based on a 10-km buffer surrounding road and train
15 transportation networks using the ESRI Data and Maps product (ESRI 2008), and a 10-km buffer surrounding
16 settlements using NLCD. Lands maintained for recreational purposes are determined from analysis of the Protected
17 Areas Database (U.S. Geological Survey 2012). The Protected Areas Database includes lands protected from
18 conversion of natural habitats to anthropogenic uses and describes the protection status of these lands. Lands are
19 considered managed that are protected from development if the regulations allow for extractive or recreational uses
20 or suppression of natural disturbance. Lands that are protected from development and not accessible to human
21 intervention, including no suppression of disturbances or extraction of resources, are not included in the managed
22 land base. Multiple data sources are used to determine lands with active resource extraction: Alaska Oil and Gas
23 Information System (Alaska Oil and Gas Conservation Commission 2009), Alaska Resource Data File (U.S.
24 Geological Survey 2012), Active Mines and Mineral Processing Plants (U.S. Geological Survey 2005), and Coal
25 Production and Preparation Report (U.S. Energy Information Administration 2011). A buffer of 3,300 and 4,000
26 meters is established around petroleum extraction and mine locations, respectively, to account for the footprint of
27 operation and impacts of activities on the surrounding landscape. The buffer size is based on visual analysis of
28 approximately 130 petroleum extraction sites and 223 mines. The resulting managed land area is overlaid on the
29 NLCD to estimate the area of managed land by land use for both federal and non-federal lands. The remaining land
30 represents the unmanaged land base. The resulting spatial product is used to identify NRI survey locations that are
31 considered managed and unmanaged for the conterminous United States and Hawaii, in addition to determining
32 which areas in the NLCD for Alaska are included in the managed land base.

33 **Approach for Combining Data Sources**

34 The managed land base in the United States has been classified into the 36 IPCC land-use/land-use conversion
35 categories using definitions developed to meet national circumstances, while adhering to IPCC (2006).²⁵ In practice,
36 the land was initially classified into a variety of land-use categories within the NRI, FIA, and NLCD datasets, and
37 then aggregated into the 36 broad land use and land-use change categories identified in IPCC (2006). All three
38 datasets provide information on forest land areas in the conterminous United States, but the area data from FIA serve
39 as the official dataset for Forest Land.

40 Therefore, another step in the analysis is to address the inconsistencies in the representation of the Forest Land
41 among the three databases. NRI and FIA have different criteria for classifying Forest Land in addition to different
42 sampling designs, leading to discrepancies in the resulting estimates of Forest Land area on non-federal land in the
43 conterminous United States. Similarly, there are discrepancies between the NLCD and FIA data for defining and
44 classifying Forest Land on federal lands. Any change in Forest Land Area in the NRI and NLCD also requires a
45 corresponding change in other land use areas because of the dependence between the Forest Land area and the
46 amount of land designated as other land uses, such as the amount of Grassland, Cropland, and Wetlands (i.e., areas
47 for the individual land uses must sum to the total managed land area of the country).

48 FIA is the main database for forest statistics, and consequently, the NRI and NLCD are adjusted to achieve
49 consistency with FIA estimates of Forest Land in the conterminous United States. Adjustments are made in the

²⁵ Definitions are provided in the previous section.

1 *Forest Land Remaining Forest Land, Land Converted to Forest Land*, and Forest Land converted to other uses (i.e.,
2 Grassland, Cropland and Wetlands). All adjustments are made at the state scale to address the differences in Forest
3 Land definitions and the resulting discrepancies in areas among the land use and land-use change categories. There
4 are three steps in this process. The first step involves adjustments for *Land Converted to Forest Land* (Grassland,
5 Cropland, and Wetlands), followed by adjustments in Forest Land converted to another land use (i.e., Grassland,
6 Cropland, and Wetlands), and finally adjustments to *Forest Land Remaining Forest Land*.

7 In the first step, *Land Converted to Forest Land* in the NRI and NLCD are adjusted to match the state-level
8 estimates in the FIA data for non-federal and federal *Land Converted to Forest Land*, respectively. FIA data do not
9 provide specific land-use categories that are converted to Forest Land, but rather a sum of all *Land Converted to*
10 *Forest Land*. The NRI and NLCD provide information on specific land use conversions, such as *Grassland*
11 *Converted to Forest Land*. Therefore, adjustments at the state level to NRI and NLCD are made proportional to the
12 amount of land use change into Forest Land for the state, prior to any adjustments. For example, if 50 percent of
13 land use change to Forest Land is associated with *Grassland Converted to Forest Land* in a state according to NRI
14 or NLCD, then half of the discrepancy with FIA data in the area of *Land Converted to Forest Land* is addressed by
15 increasing or decreasing the area in *Grassland Converted to Forest Land*. Moreover, any increase or decrease in
16 *Grassland Converted to Forest Land* in NRI or NLCD is addressed by a corresponding change in the area of
17 *Grassland Remaining Grassland*, so that the total amount of managed area is not changed within an individual state.

18 In the second step, state-level areas are adjusted in the NRI and NLCD to address discrepancies with FIA data for
19 Forest Land converted to other uses. Similar to *Land Converted to Forest Land*, FIA does not provide information
20 on the specific land-use changes, and so areas associated with Forest Land conversion to other land uses in NRI and
21 NLCD are adjusted proportional to the amount area in each conversion class in these datasets.

22 In the final step, the area of *Forest Land Remaining Forest Land* in a given state according to the NRI and NLCD is
23 adjusted to match the FIA estimates for non-federal and federal land, respectively. It is assumed that the majority of
24 the discrepancy in *Forest Land Remaining Forest Land* is associated with an under- or over-prediction of *Grassland*
25 *Remaining Grassland* and *Wetland Remaining Wetland* in the NRI and NLCD. This step also assumes that there are
26 no changes in the land use conversion categories. Therefore, corresponding increases or decreases are made in the
27 area estimates of *Grasslands Remaining Grasslands* and *Wetlands Remaining Wetlands* from the NRI and NLCD.
28 This adjustment balances the change in *Forest Land Remaining Forest Land* area, which ensures no change in the
29 overall amount of managed land within an individual state. The adjustments are based on the proportion of land
30 within each of these land-use categories at the state level (i.e., a higher proportion of Grassland led to a larger
31 adjustment in Grassland area).

32 The modified NRI data are then aggregated to provide the land-use and land-use change data for non-federal lands
33 in the conterminous United States, and the modified NLCD data are aggregated to provide the land use and land-use
34 change data for federal lands. Data for all land uses in Hawaii are based on NRI for non-federal lands and on NLCD
35 for federal lands. Land use data in Alaska are based solely on the NLCD data (Table 6-8). The result is land use and
36 land-use change data for the conterminous United States, Hawaii, and Alaska.

37 A summary of the details on the approach used to combine data sources for each land use are described below.

- 38 • *Forest Land*: Land representation for both non-federal and federal forest lands in the conterminous United
39 States and coastal Alaska are based on the FIA. FIA is used as the basis for both Forest Land area data as
40 well as to estimate C stocks and fluxes on Forest Land in the conterminous United States. FIA does have
41 survey plots in coastal Alaska that are used to determine the C stock changes, and the associated area data
42 for this region are harmonized with the NLCD using the methods described above. However, interior
43 Alaska is not currently surveyed by FIA so forest land in this region is based on the 2001 and 2011 NLCD.
44 NRI is used in the current report to provide Forest Land areas on non-federal lands in Hawaii, and NLCD is
45 used for federal lands. FIA data will be collected in Hawaii in the future.
- 46 • *Cropland*: Cropland is classified using the NRI, which covers all non-federal lands within 49 states
47 (excluding Alaska), including state and local government-owned land as well as tribal lands. NRI is used as
48 the basis for both Cropland area data as well as to estimate soil C stocks and fluxes on Cropland. NLCD is
49 used to determine Cropland area and soil C stock changes on federal lands in the conterminous United
50 States and Hawaii. NLCD is also used to determine croplands in Alaska, but C stock changes are not
51 estimated for this region in the current Inventory.

- 1 • *Grassland*: Grassland on non-federal lands is classified using the NRI within 49 states (excluding Alaska),
2 including state and local government-owned land as well as tribal lands. NRI is used as the basis for both
3 Grassland area data as well as to estimate soil C stocks and fluxes on Grassland. Grassland area and soil C
4 stock changes are determined using the classification provided in the NLCD for federal land within the
5 conterminous United States. NLCD is also used to estimate the areas of federal and non-federal grasslands
6 in Alaska, and the federal lands in Hawaii, but the current Inventory does not include C stock changes in
7 these areas.
- 8 • *Wetlands*: NRI captures wetlands on non-federal lands within 49 states (excluding Alaska), while the land
9 representation data for federal wetlands and wetlands in Alaska are based on the NLCD.²⁶
- 10 • *Settlements*: NRI captures non-federal settlement area in 49 states (excluding Alaska). If areas of Forest
11 Land or Grassland under 10 acres (4.05 ha) are contained within settlements or urban areas, they are
12 classified as Settlements (urban) in the NRI database. If these parcels exceed the 10 acre (4.05 ha) threshold
13 and are Grassland, they will be classified as such by NRI. Regardless of size, a forested area is classified as
14 non-forest by FIA if it is located within an urban area. Land representation for settlements on federal lands
15 and in Alaska is based on the NLCD.
- 16 • *Other Land*: Any land that is not classified into one of the previous five land-use categories, is categorized
17 as Other Land using the NRI for non-federal areas in the conterminous United States and Hawaii and using
18 the NLCD for the federal lands in all regions of the United States and for non-federal lands in Alaska.

19 Some lands can be classified into one or more categories due to multiple uses that meet the criteria of more than one
20 definition. However, a ranking has been developed for assignment priority in these cases. The ranking process is
21 from highest to lowest priority, in the following manner:

22 *Settlements > Cropland > Forest Land > Grassland > Wetlands > Other Land*

23 Settlements are given the highest assignment priority because they are extremely heterogeneous with a mosaic of
24 patches that include buildings, infrastructure, and travel corridors, but also open grass areas, forest patches, riparian
25 areas, and gardens. The latter examples could be classified as Grassland, Forest Land, Wetlands, and Cropland,
26 respectively, but when located in close proximity to settlement areas, they tend to be managed in a unique manner
27 compared to non-settlement areas. Consequently, these areas are assigned to the Settlements land-use category.
28 Cropland is given the second assignment priority, because cropping practices tend to dominate management
29 activities on areas used to produce food, forage, or fiber. The consequence of this ranking is that crops in rotation
30 with pasture are classified as Cropland, and land with woody plant cover that is used to produce crops (e.g.,
31 orchards) is classified as Cropland, even though these areas may meet the definitions of Grassland or Forest Land,
32 respectively. Similarly, Wetlands are considered Croplands if they are used for crop production, such as rice or
33 cranberries. Forest Land occurs next in the priority assignment because traditional forestry practices tend to be the
34 focus of the management activity in areas with woody plant cover that are not croplands (e.g., orchards) or
35 settlements (e.g., housing subdivisions with significant tree cover). Grassland occurs next in the ranking, while
36 Wetlands then Other Land complete the list.

37 The assignment priority does not reflect the level of importance for reporting greenhouse gas emissions and
38 removals on managed land, but is intended to classify all areas into a discrete land use. Currently, the IPCC does not
39 make provisions in the guidelines for assigning land to multiple uses. For example, a wetland is classified as Forest
40 Land if the area has sufficient tree cover to meet the stocking and stand size requirements. Similarly, wetlands are
41 classified as Cropland if they are used for crop production, such as rice or cranberries, or as Grassland if they are
42 composed principally of grasses, grass-like plants (i.e., sedges and rushes), forbs, or shrubs suitable for grazing and
43 browsing. Regardless of the classification, emissions from these areas are included in the Inventory if the land is
44 considered managed, and therefore impacted by anthropogenic activity in accordance with the guidance provided by
45 the IPCC (2006).

²⁶ This analysis does not distinguish between managed and unmanaged wetlands, which is a planned improvement for the Inventory.

1 QA/QC and Verification

2 The land base derived from the NRI, FIA, and NLCD was compared to the Topologically Integrated Geographic
3 Encoding and Referencing (TIGER) survey (U.S. Census Bureau 2010). The U.S. Census Bureau gathers data on the
4 U.S. population and economy, and has a database of land areas for the country. The area estimates of land-use
5 categories, based on NRI, FIA, and NLCD, are derived from remote sensing data instead of the land survey
6 approach used by the U.S. Census Survey. The U.S. Census Survey does not provide a time series of land-use
7 change data or land management information, which is needed for reporting greenhouse gas emissions from land use
8 and land use change. Regardless, the U.S. Census Survey does provide sufficient information to provide a check on
9 the Inventory data. The total difference between the U.S. Census Survey and the combined NRI, FIA, and NLCD
10 data is about 46 million hectares for the total U.S. land base of about 936 million hectares currently included in the
11 Inventory, or a 5 percent difference. Much of this difference is associated with open waters in coastal regions and
12 the Great Lakes, which is included in the TIGER Survey of the U.S. Census, but not included in the land
13 representation using the NRI, FIA and NLCD. There is only a 0.4 percent difference when open water in coastal
14 regions is removed from the TIGER data.

15 Recalculations Discussion

16 The land representation data in this Inventory changed slightly from the previous Inventory. Areas associated with
17 Forest Land changed due to updates in the FIA that also influenced the areas for Grasslands, Wetlands, and
18 Croplands through the process of harmonizing these datasets. FIA also provided area data for coastal Alaska that
19 was used in this year's analysis. In addition to the changes in the FIA data, a new NRI dataset was incorporated into
20 the current Inventory extending the time series from 2010 to 2012. The NRI program recalculated the previous time
21 series based on changes to the classification and imputation procedures for filling gaps. One of the key updates in
22 the recalculation was that the new (2012) NRI dataset had a slightly smaller land base than that reported in the 2010
23 NRI dataset, resulting in a reduction in the managed area by approximately 34,000 ha. Overall, the updates from
24 NRI and FIA led to a decrease in Forest Land area by 0.4 percent, a decrease in Cropland area by 0.3 percent, an
25 increase in Grassland area by 1.2 percent, an increase in Wetland area by 0.4 percent, a decrease in Settlements area
26 by 0.1 percent, and a decrease in Other Lands by 10 percent.

27 Planned Improvements

28 A key planned improvement for the Inventory is to fully incorporate area data by land-use type for U.S. Territories.
29 Fortunately, most of the managed land in the United States is included in the current land-use statistics, but a
30 complete accounting is a key goal for the near future. Preliminary land-use area data for U.S. Territories by land-use
31 category are provided in Box 6-2.

32 **Box 6-2: Preliminary Estimates of Land Use in U.S. Territories**

33 Several programs have developed land cover maps for U.S. Territories using remote sensing imagery, including the
34 Gap Analysis Program, Caribbean Land Cover project, National Land Cover Dataset, USFS Pacific Islands Imagery
35 Project, and the National Oceanic and Atmospheric Administration (NOAA) Coastal Change Analysis Program (C-
36 CAP). Land-cover data can be used to inform a land-use classification if there is a time series to evaluate the
37 dominant practices. For example, land that is principally used for timber production with tree cover over most of the
38 time series is classified as forest land even if there are a few years of grass dominance following timber harvest.
39 These products were reviewed and evaluated for use in the national Inventory as a step towards implementing a
40 planned improvement to include U.S. Territories in the land representation for the Inventory. Recommendations are
41 to use the NOAA C-CAP Regional Land Cover Database for the smaller island Territories (U.S. Virgin Islands,
42 Guam, Northern Marianas Islands, and American Samoa) because this program is ongoing and therefore will be
43 continually updated. The C-CAP product does not cover the entire territory of Puerto Rico so the NLCD was used
44 for this area. The final selection of a land-cover product for these territories is still under discussion. Results are
45 presented below (in hectares). The total land area of all U.S. Territories is 1.05 million hectares, representing 0.1
46 percent of the total land base for the United States.

47 **Table 6-9: Total Land Area (Hectares) by Land-Use Category for U.S. Territories**

	Puerto Rico	U.S. Virgin Islands	Guam	Northern Marianas Islands	American Samoa	Total
Cropland	19,712	138	236	289	389	20,764
Forest Land	404,004	13,107	24,650	25,761	15,440	482,962
Grasslands	299,714	12,148	15,449	13,636	1,830	342,777
Other Land	5,502	1,006	1,141	5,186	298	13,133
Settlements	130,330	7,650	11,146	3,637	1,734	154,496
Wetlands	24,525	4,748	1,633	260	87	31,252
Total	883,788	38,796	54,255	48,769	19,777	1,045,385

1
2 As adopted by the UNFCCC, new guidance in the *2013 Supplement to the 2006 Guidelines for National Greenhouse*
3 *Gas Inventories: Wetlands* will be implemented in the Inventory. As a first step in this development, greenhouse gas
4 emissions from coastal wetlands have been developed for this Inventory using the NOAA C-CAP land cover
5 product. The NOAA C-CAP product is not used directly in the land representation analysis, however, so a planned
6 improvement for the next Inventory is to reconcile the coastal wetlands data from the C-CAP product with the
7 wetlands area data provided in the NRI. Further implementation of the new guidance will have implications for the
8 classification of managed and unmanaged wetlands in the Inventory report, and more detailed wetlands datasets will
9 likely also be evaluated and integrated into the analysis.

10 NOAA C-CAP data for Hawaii were recently released for 2011, and will be used to analyze land use change for this
11 state in the near future. There are also other databases that may need to be reconciled with the NRI and NLCD
12 datasets, particularly for Settlements. Urban area estimates, used to produce C stock and flux estimates from urban
13 trees, are currently based on population data (1990, 2000, and 2010 U.S. Census data). Using the population
14 statistics, “urban clusters” are defined as areas with more than 500 people per square mile. The USFS is currently
15 moving ahead with an Urban Forest Inventory program so that urban forest area estimates will be consistent with
16 FIA forest area estimates outside of urban areas, which would be expected to reduce omissions and overlap of forest
17 area estimates along urban boundary areas.

18 **6.2 Forest Land Remaining Forest Land**

19 **Changes in Forest Carbon Stocks (IPCC Source Category 4A1)**

20 **Delineation of Carbon Pools**

21 For estimating carbon (C) stocks or stock change (flux), C in forest ecosystems can be divided into the following
22 five storage pools (IPCC 2006):

- 23 • Aboveground biomass, which includes all living biomass above the soil including stem, stump, branches,
24 bark, seeds, and foliage. This category includes live understory.
- 25 • Belowground biomass, which includes all living biomass of coarse living roots greater than 2 millimeters
26 (mm) diameter.
- 27 • Dead wood, which includes all non-living woody biomass either standing, lying on the ground (but not
28 including litter), or in the soil.
- 29 • Litter, which includes the litter, fomic, and humic layers, and all non-living biomass with a diameter less
30 than 7.5 centimeters (cm) at transect intersection, lying on the ground.
- 31 • Soil organic C (SOC), including all organic material in soil to a depth of 1 meter but excluding the coarse
32 roots of the belowground pools.

33 In addition, there are two harvested wood pools included when estimating C flux:

- 1 • Harvested wood products (HWP) in use.
- 2 • HWP in solid waste disposal sites (SWDS).

3 **Forest Carbon Cycle**

4 Carbon is continuously cycled among the previously defined C storage pools and the atmosphere as a result of
5 biogeochemical processes in forests (e.g., photosynthesis, respiration, decomposition, and disturbances such as fires
6 or pest outbreaks) and anthropogenic activities (e.g., harvesting, thinning, and replanting). As trees photosynthesize
7 and grow, C is removed from the atmosphere and stored in living tree biomass. As trees die and otherwise deposit
8 litter and debris on the forest floor, C is released to the atmosphere and is also transferred to the litter, dead wood
9 and soil pools by organisms that facilitate decomposition.

10 The net change in forest C is not equivalent to the net flux between forests and the atmosphere because timber
11 harvests do not cause an immediate flux of all harvested biomass C to the atmosphere. Instead, harvesting transfers a
12 portion of the C stored in wood to a "product pool." Once in a product pool, the C is emitted over time as CO₂ in the
13 case of decomposition and as CO₂, CH₄, N₂O, CO, NO_x when the wood product combusts. The rate of emission
14 varies considerably among different product pools. For example, if timber is harvested to produce energy,
15 combustion releases C immediately, and these emissions are reported for information purposes in the Energy sector
16 while the harvest (i.e., the associated reduction in forest C stocks) and subsequent combustion are implicitly
17 estimated in the Land Use, Land-Use Change, and Forestry (LULUCF) sector (i.e., the harvested timber does not
18 enter the HWP pools). Conversely, if timber is harvested and used as lumber in a house, it may be many decades or
19 even centuries before the lumber decays and C is released to the atmosphere. If wood products are disposed of in
20 SWDS, the C contained in the wood may be released many years or decades later, or may be stored almost
21 permanently in the SWDS. These latter fluxes, with the exception of CH₄ from wood in SWDS which is included in
22 the Waste sector, are also estimated in the LULUCF sector.

23 **Net Change in Carbon Stocks within Forest Land of the United States**

24 This section describes the general method for quantifying the net changes in C stocks in the five forest C pools and
25 two harvested wood pools. The underlying methodology for determining C stock and stock-change relies on data
26 from the Forest Inventory and Analysis (FIA) program within the USDA Forest Service. The annual forest inventory
27 system is implemented across all U.S. forest lands within the conterminous 48 states, but at this time does not
28 include interior Alaska, Hawaii, and U.S. Territories. The methods for estimation and monitoring are continuously
29 improved and these improvements are reflected in the C estimates (Domke et al. 2016; Domke et al. In press). First,
30 the total C stocks are estimated for each pool, next the net changes in C stocks for each pool are estimated, and then
31 the changes in stocks are summed for all pools to estimate total net flux. The focus on C implies that all C-based
32 greenhouse gases are included, and the focus on stock change suggests that specific ecosystem fluxes do not need to
33 be separately itemized in this report. Changes in C stocks from disturbances, such as forest fires or harvesting, are
34 included in the net changes. For instance, an inventory conducted after fire counts only the trees that are left.
35 Therefore, changes in C stocks from natural disturbances, such as wildfires, pest outbreaks, and storms, are included
36 in the forest inventory approach; however, they are highly variable from year to year. The IPCC (2006) recommends
37 estimating changes in C stocks from forest lands according to several land-use types and conversions, specifically
38 *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*, with the former being lands that have
39 been forest lands for 20 years or longer and the latter being lands that have been classified as forest lands for less
40 than 20 years. The methods and data used to delineate forest C stock changes by these two categories continue to
41 improve and in order to facilitate this delineation, a combination of modeling approaches for carbon estimation were
42 used this year in the U.S.

43 **Forest Area in the United States**

44 Approximately 33 percent of the U.S. land area is estimated to be forested in 2015 based on the U.S. definition of
45 forest land as provided in the Section 6.1 Representation of the U.S. Land Base. The most recent forest inventories
46 from each of the conterminous 48 states (USDA Forest Service 2016a, 2016b) comprise an estimated 266 million
47 hectares of forest land that are considered managed and are included in this Inventory. An additional 6.2 million
48 hectares of forest land in southeast and south central coastal Alaska are inventoried and are also included here. Some
49 differences exist in forest land area estimates from the latest update to the Resources Planning Act (RPA)

1 Assessment (Oswalt et al. 2014) and the forest land area estimates included in this report, which are based on the
2 most recent annual inventory data available for all states (USDA Forest Service 2016b). Sufficient annual inventory
3 data are not yet available for Hawaii and interior Alaska, but estimates of these areas are included in Oswalt et al.
4 (2014). Updated survey data for central and western forest land in both Oklahoma and Texas have only recently
5 become available, and these forests contribute to overall C stocks reported below. While Hawaii and U.S. Territories
6 have relatively small areas of forest land and thus may not substantially influence the overall C budget for forest
7 land, these regions will be added to the forest C estimates as sufficient data become available. Agroforestry systems
8 that meet the definition of forest land are also not currently included in this Inventory since they are not explicitly
9 inventoried by either the FIA program or the Natural Resources Inventory (NRI)²⁷ of the USDA Natural Resources
10 Conservation Service (Perry et al. 2005).

11 An estimated 77 percent (211 million hectares) of U.S. forests in southeast and southcentral coastal Alaska and the
12 conterminous United States are classified as timberland, meaning they meet minimum levels of productivity and
13 have not been removed from production. Approximately ten percent of southeast and southcentral coastal Alaska
14 forest land and 80 percent of forest land in the conterminous United States are classified as timberland. Of the
15 remaining non-timberland, 30 million hectares are reserved forest lands (withdrawn by law from management for
16 production of wood products) and 69 million hectares are lower productivity forest lands (Oswalt et al. 2014).
17 Historically, the timberlands in the conterminous 48 states have been more frequently or intensively surveyed than
18 the forest land removed from production because it does not meet the minimum level of productivity.

19 Since the late 1980s, forest land area in southeast and southcentral coastal Alaska and the conterminous U.S. has
20 increased by about 14 million hectares (Oswalt et al. 2014) with the southern region of the U.S. containing the most
21 forest land (Figure 6-2). A substantial portion of this accrued forest land is from the conversion of abandoned
22 croplands to forest (e.g., Woodall et al. 2015b). Current trends in the estimated forest land area in the conterminous
23 U.S. and the portion of southeast and south central coastal Alaska represented here show an average annual rate of
24 increase of 0.1 percent. In addition to the increase in forest area, the major influences to the net C flux from forest
25 land across the 1990 to 2015 time series are management activities and the ongoing impacts of previous land-use
26 conversions. These activities affect the net flux of C by altering the amount of C stored in forest ecosystems and also
27 the area converted to forest land. For example, intensified management of forests that leads to an increased rate of
28 growth of aboveground biomass (and possible changes to the other C pools) may increase the eventual biomass
29 density of the forest, thereby increasing the uptake and storage of C in the aboveground biomass pool.²⁸ Though
30 harvesting forests removes much of the C in aboveground biomass (and possibly changes C density in other pools),
31 on average, the estimated volume of annual net growth in the conterminous U.S. states is about double the volume
32 of annual removals on timberlands (Oswalt et al. 2014). The net effects of forest management and changes in *Forest*
33 *Land Remaining Forest Land* are captured in the estimates of C stocks and fluxes presented in this section.

²⁷ The Natural Resources Inventory of the USDA Natural Resources Conservation Service is described in Section 6.1—
Representation of the U.S. Land Base.

²⁸ The term “biomass density” refers to the mass of live vegetation per unit area. It is usually measured on a dry-weight basis.
Dry biomass is assumed to be 50 percent C by weight.

 2 **conterminous United States and coastal Alaska (1990-2015, Million Hectares)**

3
 4 ***Forest Carbon Stocks and Stock Change***

5 In the U.S., forest management practices, the regeneration of forest areas cleared more than 20 years prior to the
 6 reporting year, and timber harvesting have resulted in net uptake (i.e., net sequestration) of C each year from 1990
 7 through 2015. The rate of forest clearing in the 17th century following European settlement had slowed by the late
 8 19th century. Through the later part of the 20th century many areas of previously forested land in the U.S. were
 9 allowed to revert to forests or were actively reforested. The impacts of these land-use changes still influence C
 10 fluxes from these forest lands. More recently, the 1970s and 1980s saw a resurgence of federally-sponsored forest
 11 management programs (e.g., the Forestry Incentive Program) and soil conservation programs (e.g., the Conservation
 12 Reserve Program), which have focused on tree planting, improving timber management activities, combating soil
 13 erosion, and converting marginal cropland to forests. In addition to forest regeneration and management, forest
 14 harvests have also affected net C fluxes. Because most of the timber harvested from U.S. forest land is used in wood
 15 products, and many discarded wood products are disposed of in SWDS rather than by incineration, significant
 16 quantities of C in harvested wood are transferred to these long-term storage pools rather than being released rapidly
 17 to the atmosphere (Skog 2008). With sustainable harvesting practices and regeneration of these forested lands, along
 18 with continued input of harvested products into the HWP pool, C stocks in the *Forest Land Remaining Forest Land*
 19 category are likely to continue to increase in the near term, though possibly at a lower rate. Changes in C stocks in
 20 the forest and harvested wood pools associated with *Forest Land Remaining Forest Land* were estimated to result in

net sequestration of 667.0 MMT CO₂ Eq. (181.9 MMT C) in 2015 (Table 6-10 and Table 6-11).²⁹ Overall, estimates of average C density in forest ecosystems (including all pools) remained stable at approximately 0.0002 MMT C ha⁻¹ from 1990 to 2015 (Table 6-12). The stable forest ecosystem C density when combined with increasing forest area results in net C accumulation over time. These increases may be influenced in some regions by reductions in C density or forest land area due to natural disturbances (e.g., wildfire, weather, insects/disease). Aboveground live biomass is responsible for the majority of net sequestration among all forest ecosystem pools (Figure 6-4).

The estimated net sequestration of C in HWP was 95.9 MMT CO₂ Eq. (26.1 MMT C) in 2015 (Table 6-10 and Table 6-11). The majority of this sequestration, 64.4 MMT CO₂ Eq. (17.6 MMT C), was from wood and paper in SWDS. Products in use were an estimated 31.4 MMT CO₂ Eq. (8.6 MMT C) in 2015.

Table 6-10: Net CO₂ Flux from Forest Pools in *Forest Land Remaining Forest Land* and *Harvested Wood Pools* (MMT CO₂ Eq.)

Carbon Pool	1990	2005	2011	2012	2013	2014	2015
Forest	(574.7)	(557.3)	(605.0)	(598.5)	(596.1)	(593.7)	(571.1)
Aboveground Biomass	(327.9)	(314.4)	(337.2)	(331.5)	(329.6)	(327.7)	(310.0)
Belowground Biomass	(70.0)	(66.6)	(71.0)	(69.7)	(69.2)	(68.7)	(64.6)
Dead Wood	(33.5)	(40.3)	(48.5)	(49.1)	(49.2)	(49.2)	(43.7)
Litter	(17.0)	(14.3)	(16.5)	(16.3)	(16.3)	(16.3)	(15.2)
Soil (Mineral)	(126.1)	(121.7)	(131.9)	(132.0)	(131.9)	(131.9)	(137.6)
Soil (Organic) ^a	(0.1)	+	0.1	0.1	0.1	0.1	0.1
Harvested Wood	(123.8)	(108.0)	(65.7)	(69.2)	(75.6)	(76.4)	(95.9)
Products in Use	(54.8)	(44.6)	(3.9)	(7.0)	(13.0)	(13.7)	(31.4)
SWDS	(69.0)	(63.5)	(61.8)	(62.2)	(62.6)	(62.7)	(64.4)
Total Net Flux	(698.4)	(665.3)	(670.8)	(667.8)	(671.7)	(670.1)	(667.0)

+ Absolute value does not exceed 0.05 MMT CO₂ Eq.

^aThese estimates do not include drained organic soils. See Table 6-21 and Table 6-22 for emissions from drainage of organic soils from *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*.

Note: Forest C stocks do not include forest stocks in U.S. Territories, Hawaii, a portion of managed forests in Alaska, or trees on non-forest land (e.g., urban trees, agroforestry systems). Parentheses indicate net C sequestration (i.e., a net removal of C from the atmosphere). Total net flux is an estimate of the actual net flux between the total forest C pool and the atmosphere. Harvested wood estimates are based on results from annual surveys and models. Totals may not sum due to independent rounding.

Table 6-11: Net C Flux from Forest Pools in *Forest Land Remaining Forest Land* and *Harvested Wood Pools* (MMT C)

Carbon Pool	1990	2005	2011	2012	2013	2014	2015
Forest	(156.7)	(152.0)	(165.0)	(163.2)	(162.6)	(161.9)	(155.7)
Aboveground Biomass	(89.4)	(85.7)	(92.0)	(90.4)	(89.9)	(89.4)	(84.6)
Belowground Biomass	(19.1)	(18.2)	(19.4)	(19.0)	(18.9)	(18.7)	(17.6)
Dead Wood	(9.1)	(11.0)	(13.2)	(13.4)	(13.4)	(13.4)	(11.9)
Litter	(4.6)	(3.9)	(4.5)	(4.4)	(4.4)	(4.4)	(4.1)
Soil (Mineral)	(34.4)	(33.2)	(36.0)	(36.0)	(36.0)	(36.0)	(37.5)
Soil (Organic) ^a	+	+	+	+	+	+	+
Harvested Wood	(33.8)	(29.5)	(17.9)	(18.9)	(20.6)	(20.8)	(26.1)
Products in Use	(14.9)	(12.2)	(1.1)	(1.9)	(3.5)	(3.7)	(8.6)
SWDS	(18.8)	(17.3)	(16.9)	(17.0)	(17.1)	(17.1)	(17.6)
Total Net Flux	(190.5)	(181.5)	(183.0)	(182.1)	(183.2)	(182.8)	(181.9)

+ Absolute value does not exceed 0.05 MMT C

^aThese estimates do not include drained organic soils. See Tables 6.20 and 6.21 for emission from drainage of organic soils from *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*.

²⁹ It is important to note that litter and soil C stock and stock change estimates reported in the 1990–2014 Inventory were inadvertently compiled using English units resulting in estimates that were 2.2417 times larger than they should have been for the *Forest Land Remaining Forest Land* category. Please see the Recalculations Discussion and the QA/QC and Verifications sections for additional details.

Note: Forest C stocks do not include forest stocks in U.S. Territories, Hawaii, a portion of managed lands in Alaska, or trees on non-forest land (e.g., urban trees, agroforestry systems). Parentheses indicate net C sequestration (i.e., a net removal of C from the atmosphere). Total net flux is an estimate of the actual net flux between the total forest C pool and the atmosphere. Harvested wood estimates are based on results from annual surveys and models. Totals may not sum due to independent rounding.

1 Stock estimates for forest and harvested wood C storage pools are presented in Table 6-12. Together, the estimated
 2 aboveground biomass and soil C pools account for a large proportion of total forest C stocks. Note that the forest
 3 land area estimates in Table 6-12 do not precisely match those in Section 6.1 Representation of the U.S. Land Base
 4 for *Forest Land Remaining Forest Land*. This is because the forest land area estimates in Table 6-12 only include
 5 managed forest land in the conterminous 48 states and southeast and south central coastal Alaska (which is the
 6 current area encompassed by FIA survey data, approximately 6.2 million ha) while the area estimates in Section 6.1
 7 include all managed forest land in Alaska (approximately 25.9 million ha with approximately 19.7 million ha in
 8 interior Alaska which is not currently included in this Inventory) and Hawaii.

9 **Table 6-12: Forest Area (1,000 ha) and C Stocks in *Forest Land Remaining Forest Land* and**
 10 **Harvested Wood Pools (MMT C)**

	1990	2005	2011	2012	2013	2014	2015	2016
<i>Forest Area (1000 ha)</i>	262,119	267,479	270,654	271,064	271,512	271,812	272,113	272,260
Carbon Pools (MMT C)

Aboveground Biomass	11,889	13,122	13,650	13,742	13,833	13,922	14,012	14,096
Belowground Biomass	2,439	2,700	2,812	2,831	2,850	2,869	2,888	2,905
Dead Wood	2,262	2,424	2,494	2,507	2,521	2,534	2,548	2,560
Litter	2,568	2,630	2,654	2,659	2,663	2,668	2,672	2,676
Soil (Mineral)	27,456	27,994	28,204	28,240	28,276	28,312	28,348	28,385
Soil (Organic) ^a	352	352	352	352	352	352	352	352
Harvested Wood	1,895	2,353	2,481	2,498	2,517	2,538	2,559	2,585
Products in Use	1,249	1,447	1,473	1,474	1,476	1,479	1,483	1,492
SWDS	646	906	1,008	1,025	1,042	1,059	1,076	1,093
Total C Stock	48,862	51,576	52,647	52,830	53,012	53,195	53,378	53,560

^aThese estimates do not include drained organic soils. See Table 6-21 and Table 6-22 for emissions from drainage of organic soils from *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*.

Note: Forest area and C stock estimates include all *Forest Land Remaining Forest Land* in the conterminous 48 states and southeast and south central coastal Alaska (6.2 million ha), which is the current area encompassed by FIA survey data. Forest C stocks do not include forest stocks in U.S. Territories, Hawaii, a large portion of interior Alaska (19.7 million ha), or trees on non-forest land (e.g., urban trees, agroforestry systems). The forest area estimates in this table do not match those in Section 6.1 Representation of the U.S. Land Base, which includes all managed forest land in Alaska and Hawaii. Harvested wood product stocks include exports, even if the logs are processed in other countries, and exclude imports. Harvested wood estimates are based on results from annual surveys and models. Totals may not sum due to independent rounding. Population estimates compiled using FIA data are assumed to represent stocks as of January 1 of the Inventory year. Flux is the net annual change in stock. Thus, an estimate of flux for 2015 requires estimates of C stocks for 2015 and 2016.

1 **Figure 6-3: Estimated Net Annual Changes in C Stocks for All C Pools in *Forest Land***
 2 ***Remaining Forest Land* in the Conterminous U.S. and Coastal Alaska (MMT C per Year)**

3
4

5 **Box 6-3: CO₂ Emissions from Forest Fires**

6 As stated previously, the forest inventory approach implicitly includes all C losses due to disturbances such as forest
 7 fires, because only C remaining in the forest is estimated. Net C stock change is estimated by subtracting
 8 consecutive C stock estimates. A forest fire disturbance removes C from the forest. The inventory data on which net
 9 C stock estimates are based already reflect this C loss. Therefore, estimates of net annual changes in C stocks for
 10 U.S. forest land already includes CO₂ emissions from forest fires occurring in the conterminous states as well as the
 11 portion of managed forest lands in Alaska that are captured in this Inventory. Because it is of interest to quantify the
 12 magnitude of CO₂ emissions from fire disturbance, these separate estimates are highlighted here. Note that these
 13 CO₂ estimates are based on the same methodology as applied for the non-CO₂ greenhouse gas emissions from forest
 14 fires that are also quantified in a separate section below as required by IPCC Guidance and UNFCCC Reporting
 15 Requirements.

16 The IPCC (2006) methodology and a combination of U.S.-specific data on annual area burned and potential fuel
 17 availability together with default combustion factors were employed to estimate CO₂ emissions from forest fires.
 18 CO₂ emissions for wildfires in the conterminous 48 states and in Alaska as well as prescribed fires in 2015 were
 19 estimated to be 96.3 MMT CO₂ per year (Table 6-13). This quantity is an embedded component of the net annual
 20 forest C stock change estimates provided previously (i.e., Table 6-11), but this separate approach to estimate
 21 emissions is necessary in order to associate a portion of emissions, including estimates of CH₄ and N₂O, with fire.
 22 See the discussion in Annex 3.13 for more details on this methodology. Note that the estimates for Alaska provided

1 in Table 6-13 include all managed forest land in the state and are not limited to the subset with permanent inventory
 2 plots on managed lands as specified elsewhere in this chapter (i.e., Table 6-11).

3 **Table 6-13: Estimates of CO₂ (MMT per Year) Emissions from Forest Fires in the**
 4 **Conterminous 48 States and Alaska^a**

Year	CO ₂ emitted from Wildfires in the Conterminous 48 States (MMT yr ⁻¹)	CO ₂ emitted from Wildfires in Alaska (MMTyr ⁻¹)	CO ₂ emitted from Prescribed Fires (MMTyr ⁻¹)	Total CO ₂ emitted (MMTyr ⁻¹)
1990	22.7	19.5	0.2	42.4
2005	43.5	80.1	1.3	124.9
2011	81.3	3.6	6.0	90.9
2012	138.0	2.7	3.0	143.6
2013	68.0	22.3	5.5	95.7
2014	85.3	4.9	6.1	96.3
2015 ^b	85.3	4.9	6.1	96.3

^a These emissions have already been included in the estimates of net annual changes in C stocks, which include the amount sequestered minus any emissions, including the assumption that combusted wood may continue to decay through time.

^b The data for 2015 were incomplete when these estimates were summarized; therefore 2014, the most recent available estimate, is applied to 2015.

5

6 Methodology and Data Sources

7 The methodology described herein is consistent with IPCC (2006). Forest ecosystem C stocks and net annual C
 8 stock change were determined according to the stock-difference method, which involved applying C estimation
 9 factors to annual forest inventories across time to obtain C stocks and then subtracting between the years to obtain
 10 the stock change. Harvested wood C estimates were based on factors such as the allocation of wood to various
 11 primary and end-use products as well as half-life (the time at which half of the amount placed in use will have been
 12 discarded from use) and expected disposition (e.g., product pool, SWDS, combustion). An overview of the different
 13 methodologies and data sources used to estimate the C in forest ecosystems or harvested wood products is provided
 14 here. See Annex 3.13 for details and additional information related to the methods and data.

15 *Forest Ecosystem Carbon from Forest Inventory*

16 The U.S. applied the compilation approach used in the 1990 to 2014 Inventory and described in Woodall et al.
 17 (2015a) for this Inventory which removes the older periodic inventory data, which may be inconsistent with annual
 18 inventory data, from the estimation procedures and enables the delineation of forest C accumulation by forest
 19 growth, land use change, and natural disturbances such as fire. Development will continue on a system that
 20 attributes changes in forest C to disturbances and delineates *Land Converted to Forest Land* from *Forest Land*
 21 *Remaining Forest Land*. As part of this development, C pool science will continue and will be expanded to include
 22 C stock transfers from forest land to other land uses, and include techniques to better identify land use change (see
 23 the Planned Improvements section below).

24 Unfortunately, the annual inventory system does not extend into the 1990s, necessitating the adoption of a system to
 25 “backcast” the annual C estimates. To facilitate the backcasting of the U.S. annual forest inventory C estimates, the
 26 estimation system used in this Inventory is comprised of a forest dynamics module (age transition matrices) and a
 27 land use dynamics module (land area transition matrices). The forest dynamics module assesses forest sequestration,
 28 forest aging, and disturbance effects (e.g., disturbances such as wind, fire, and floods identified by foresters on
 29 inventory plots). The land use dynamics module assesses C stock transfers associated with afforestation and
 30 deforestation (Woodall et al. 2015b). Both modules are developed from land use area statistics and C stock change
 31 or C stock transfer by age class. The required inputs are estimated from more than 625,000 forest and non-forest

1 observations recorded in the FIA national database (U.S. Forest Service 2016a, b, c). Model predictions prior to the
2 annual inventory period are constructed from the estimation system using the annual estimates. The estimation
3 system is driven by the annual forest inventory system conducted by the FIA program (Frayer and Furnival 1999;
4 Bechtold and Patterson 2005; USDA Forest Service 2016d, 2016a). The FIA program relies on a rotating panel
5 statistical design with a sampling intensity of one 674.5 m² ground plot per 2,403 ha of land and water area. A five-
6 panel design, with 20 percent of the field plots typically measured each year within a state, is used in the eastern
7 United States and a ten-panel design, with 10 percent of the field plots measured each year within a state, is used in
8 the western United States. The interpenetrating hexagonal design across the U.S. landscape enables the sampling of
9 plots at various intensities in a spatially and temporally unbiased manner. Typically, tree and site attributes are
10 measured with higher sample intensity while other ecosystem attributes such as downed dead wood are sampled
11 during summer months at lower intensities. The first step in incorporating FIA data into the estimation system is to
12 identify annual inventory datasets by state. Inventories include data collected on permanent inventory plots on forest
13 lands and were organized as separate datasets, each representing a complete inventory, or survey, of an individual
14 state at a specified time. Many of the annual inventories reported for states are represented as “moving window”
15 averages, which mean that a portion—but not all—of the previous year’s inventory is updated each year (USDA
16 Forest Service 2016d). Forest C estimates are organized according to these state surveys, and the frequency of
17 surveys varies by state.

18 Using this FIA data, separate estimates were prepared for the five C storage pools identified by IPCC (2006) and
19 described above. All estimates were based on data collected from the extensive array of permanent, annual forest
20 inventory plots and associated models (e.g., live tree belowground biomass) in the U.S. (USDA Forest Service
21 2016b, 2016c). Carbon conversion factors were applied at the disaggregated level of each inventory plot and then
22 appropriately expanded to population estimates.

23 *Carbon in Biomass*

24 Live tree C pools include aboveground and belowground (coarse root) biomass of live trees with diameter at breast
25 height (dbh) of at least 2.54 cm at 1.37 m above the litter. Separate estimates were made for above- and
26 belowground biomass components. If inventory plots included data on individual trees, aboveground and
27 belowground (coarse roots) tree C was based on Woodall et al. (2011a), which is also known as the component ratio
28 method (CRM), and is a function of tree volume, species, and diameter. An additional component of foliage, which
29 was not explicitly included in Woodall et al. (2011a), was added to each tree following the same CRM method.

30 Understory vegetation is a minor component of biomass, which is defined in the FIA program as all biomass of
31 undergrowth plants in a forest, including woody shrubs and trees less than 2.54 cm dbh. For this Inventory, it was
32 assumed that 10 percent of total understory C mass is belowground (Smith et al. 2006). Estimates of C density were
33 based on information in Birdsey (1996) and biomass estimates from Jenkins et al. (2003). Understory biomass
34 represented over one percent of C in biomass, but its contribution rarely exceeded 2 percent of the total carbon
35 stocks or stock changes across all forest ecosystem C pools each year.

36 *Carbon in Dead Organic Matter*

37 Dead organic matter was initially calculated as three separate pools—standing dead trees, downed dead wood, and
38 litter—with C stocks estimated from sample data or from models as described below. The standing dead tree C pool
39 includes aboveground and belowground (coarse root) biomass for trees of at least 12.7 cm dbh. Calculations
40 followed the basic method applied to live trees (Woodall et al. 2011a) with additional modifications to account for
41 decay and structural loss (Domke et al. 2011; Harmon et al. 2011). Downed dead wood estimates are based on
42 measurement of a subset of FIA plots for downed dead wood (Domke et al. 2013; Woodall and Monleon 2008;
43 Woodall et al. 2013). Downed dead wood is defined as pieces of dead wood greater than 7.5 cm diameter, at transect
44 intersection, that are not attached to live or standing dead trees. This includes stumps and roots of harvested trees.
45 To facilitate the downscaling of downed dead wood C estimates from the state-wide population estimates to
46 individual plots, downed dead wood models specific to regions and forest types within each region are used. Litter C
47 is the pool of organic C (also known as duff, humus, and fine woody debris) above the mineral soil and includes
48 woody fragments with diameters of up to 7.5 cm. A subset of FIA plots are measured for litter C. A modeling
49 approach, using litter C measurements from FIA plots (Domke et al. 2016) was used to estimate litter C for every
50 FIA plot used in the estimation framework.

1 *Carbon in Forest Soil*

2 Soil carbon is the largest terrestrial C sink with much of that C in forest ecosystems. The FIA program has been
3 consistently measuring soil attributes as part of the annual inventory since 2001 and has amassed an extensive
4 inventory of soil measurement data on forest land in the conterminous U.S. and coastal Alaska (O'Neill et al. 2005).
5 Observations of mineral and organic soil C on forest land from the FIA program and the International Soil Carbon
6 Monitoring Network were used to develop and implement a modeling approach that enabled the prediction of
7 mineral and organic soil C to a depth of 100 cm from empirical measurements to a depth of 20 cm and included site-
8 , stand-, and climate-specific variables that yield predictions of soil C stocks specific to forest land in the United
9 States (Domke et al. In press). This new approach allowed for separation of mineral and organic soils also referred
10 to as *Histosols* for the first time in the *Forest Land Remaining Forest Land* category. Note that mineral and organic
11 soil C is reported to a depth of 100 cm for *Forest Land Remaining Forest Land* to remain consistent with past
12 reporting in this category, however for consistency across land-use categories mineral soil C is reported to a depth of
13 30 cm in Section 6.3 *Land Converted to Forest Land*. Estimates of C from organic soils in this section (Table 6-10,
14 Table 6-11, and Table 6-12) do not include emissions from drained organic soils. Estimates of emissions from
15 drainage of organic soils from *Forest Land Remaining Forest Land* and *Land Converted to Forest Land* can be
16 found in the Drained Organic Soils section below (Table 6-21 and Table 6-22).

17 *Harvested Wood Carbon*

18 Estimates of the HWP contribution to forest C sinks and emissions (hereafter called “HWP contribution”) were
19 based on methods described in Skog (2008) using the WOODCARB II model. These methods are based on IPCC
20 (2006) guidance for estimating the HWP contribution. IPCC (2006) provides methods that allow for reporting of
21 HWP contribution using one of several different methodological approaches: Production, stock change and
22 atmospheric flow, as well as a default method that assumes there is no change in HWP C stocks (see Annex 3.13 for
23 more details about each approach). The U.S. uses the production approach to report HWP contribution. Under the
24 production approach, C in exported wood was estimated as if it remains in the U.S., and C in imported wood was not
25 included in the estimates. Though reported U.S. HWP estimates are based on the production approach, estimates
26 resulting from use of the two alternative approaches, the stock change and atmospheric flow approaches, are also
27 presented for comparison (see Annex 3.13). Annual estimates of change were calculated by tracking the annual
28 estimated additions to and removals from the pool of products held in end uses (i.e., products in use such as housing
29 or publications) and the pool of products held in SWDS. Emissions from HWP associated with wood biomass
30 energy are not included in this section of the Inventory—a net of zero sequestration and emissions as they are a part
31 of the Energy sector reporting (see Chapter 3).

32 Solidwood products include lumber and panels. End-use categories for solidwood include single and multifamily
33 housing, alteration and repair of housing, and other end-uses. There is one product category and one end-use
34 category for paper. Additions to and removals from pools were tracked beginning in 1900, with the exception that
35 additions of softwood lumber to housing, which began in 1800. Solidwood and paper product production and trade
36 data were taken from USDA Forest Service and other sources (Hair and Ulrich 1963; Hair 1958; USDC Bureau of
37 Census 1976; Ulrich 1985, 1989; Steer 1948; AF&PA 2006a, 2006b; Howard 2003, 2007, 2016, In preparation).
38 Estimates for disposal of products reflected the change over time in the fraction of products discarded to SWDS (as
39 opposed to burning or recycling) and the fraction of SWDS that were in sanitary landfills versus dumps.

40 There are five annual HWP variables that were used in varying combinations to estimate HWP contribution using
41 any one of the three main approaches listed above. These are:

- 42 (1A) annual change of C in wood and paper products in use in the U.S.,
- 43 (1B) annual change of C in wood and paper products in SWDS in the U.S.,
- 44 (2A) annual change of C in wood and paper products in use in the U.S. and other countries where the wood
45 came from trees harvested in the U.S.,
- 46 (2B) annual change of C in wood and paper products in SWDS in the U.S. and other countries where the
47 wood came from trees harvested in the U.S.,
- 48 (3) C in imports of wood, pulp, and paper to the U.S.,
- 49 (4) C in exports of wood, pulp and paper from the U.S., and

1 (5) C in annual harvest of wood from forests in the U.S.

2 The sum of variables 2A and 2B yielded the estimate for HWP contribution under the production estimation
3 approach. A key assumption for estimating these variables was that products exported from the U.S. and held in
4 pools in other countries have the same half-lives for products in use, the same percentage of discarded products
5 going to SWDS, and the same decay rates in SWDS as they would in the U.S.

6 **Uncertainty and Time-Series Consistency**

7 A quantitative uncertainty analysis placed bounds on current flux for forest ecosystems through a combination of
8 sample-based and model-based approaches to uncertainty for forest ecosystem CO₂ flux (IPCC Approach 1). A
9 Monte Carlo Stochastic Simulation of the Methods described above and probabilistic sampling of C conversion
10 factors were used to determine the HWP uncertainty (IPCC Approach 2). See Annex 3.13 for additional information.
11 The 2015 net annual change for forest C stocks was estimated to be between -898.5 and -397.2 MMT CO₂ Eq.
12 around a central estimate of -666.9 MMT CO₂ Eq. at a 95 percent confidence level. This includes a range of -820.3
13 to -321.9 MMT CO₂ Eq. around a central estimate of -571.1 MMT CO₂ Eq. for forest ecosystems and -115.1 to -
14 76.6 MMT CO₂ Eq. around a central estimate of -95.9 MMT CO₂ Eq. for HWP.

15 **Table 6-14: Quantitative Uncertainty Estimates for Net CO₂ Flux from *Forest Land***
16 ***Remaining Forest Land: Changes in Forest C Stocks (MMT CO₂ Eq. and Percent)***

Source	Gas	2015 Flux Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Flux Estimate			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Forest C Pools ^a	CO ₂	(571.1)	(820.3)	(321.9)	-43.6%	43.6%
Harvested Wood Products ^b	CO ₂	(95.9)	(115.1)	(76.6)	-20.1%	20.1%
Total Forest	CO₂	(667.0)	(916.9)	(417.0)	-37.5%	37.5%

^aRange of flux estimates predicted through a combination of sample based and model based uncertainty for a 95 percent confidence interval, IPCC Approach 1.

^bRange of flux estimates predicted by Monte Carlo stochastic simulation for a 95 percent confidence interval, IPCC Approach 2.

Note: Parentheses indicate negative values or net sequestration.

17 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
18 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
19 above.

20 **QA/QC and Verification**

21 As discussed above, the FIA program has conducted consistent forest surveys based on extensive statistically-based
22 sampling of most of the forest land in the conterminous United States, dating back to 1952. The FIA program
23 includes numerous quality assurance and quality control (QA/QC) procedures, including calibration among field
24 crews, duplicate surveys of some plots, and systematic checking of recorded data. Because of the statistically-based
25 sampling, the large number of survey plots, and the quality of the data, the survey databases developed by the FIA
26 program form a strong foundation for C stock estimates. Field sampling protocols, summary data, and detailed
27 inventory databases are archived and are publicly available on the Internet (USDA Forest Service 2016d).

28 General quality control procedures were used in performing calculations to estimate C stocks based on survey data.
29 For example, the C datasets, which include inventory variables such as areas and volumes, were compared to
30 standard inventory summaries such as the forest resource statistics of Oswalt et al. (2014) or selected population
31 estimates generated from the FIA database, which are available at an FIA internet site (USDA Forest Service
32 2016b). Agreement between the C datasets and the original inventories is important to verify accuracy of the data
33 used. Estimates were also compiled using an FIADB-to-C calculator (Smith et al. 2010) and compared with
34 estimates compiled using the current estimation system. During the implementation of this additional QA step in
35 preparation of this Inventory, a mistake in the unit conversion code used to compile plot-level estimates of C stocks
36 and stock changes from the FIADB was discovered. Specifically, the litter and soil carbon stock and stock change

1 estimates reported in the 1990 to 2014 Inventory were inadvertently compiled using English units resulting in
2 estimates that were 2.2417 times larger than they should have been for the *Forest Land Remaining Forest Land*
3 category. This mistake was not caught last year since the soil carbon model and the estimation system used to
4 compile estimates for the U.S. were both being used for the first time with no similar estimates (e.g., national-level
5 population estimates using similar data) available for comparison. This mistake has been corrected in this Inventory.
6 Finally, C stock estimates for this Inventory were compared with previous Inventory report estimates to ensure that
7 any differences could be explained by either new data or revised calculation methods (see the Recalculations
8 discussion, below). As previously mentioned, the litter and soil C stock and stock change estimates from the 1990 to
9 2014 Inventory must be divided by 2.2417 to put them in the correct units for comparison with estimates in the
10 current Inventory.

11 Estimates of the HWP variables and the HWP contribution under the production estimation approach use data from
12 U.S. Census and USDA Forest Service surveys of production and trade and other sources (Hair and Ulrich 1963;
13 Hair 1958; USDC Bureau of Census 1976; Ulrich 1985, 1989; Steer 1948; AF&PA 2006a, 2006b; Howard 2003,
14 2007, 2016, In preparation). Factors to convert wood and paper to units of C are based on estimates by industry and
15 Forest Service published sources (see Annex 3.13 and Table A-240 and A-241). The WOODCARB II model uses
16 estimation methods suggested by IPCC (2006). Estimates of annual C change in solidwood and paper products in
17 use were calibrated to meet two independent criteria. The first criterion is that the WOODCARB II model estimate
18 of C in houses standing in 2001 needs to match an independent estimate of C in housing based on U.S. Census and
19 USDA Forest Service survey data. Meeting the first criterion resulted in an estimated half-life of about 80 years for
20 single family housing built in the 1920s, which is confirmed by other U.S. Census data on housing. The second
21 criterion is that the WOODCARB II model estimate of wood and paper being discarded to SWDS needs to match
22 EPA estimates of discards used in the Waste sector each year over the period 1990 to 2000 (EPA 2006). These
23 criteria help reduce uncertainty in estimates of annual change in C in products in use in the U.S. and, to a lesser
24 degree, reduce uncertainty in estimates of annual change in C in products made from wood harvested in the U.S. In
25 addition, WOODCARB II landfill decay rates have been validated by ensuring that estimates of CH₄ emissions from
26 landfills based on EPA (2006) data are reasonable in comparison to CH₄ estimates based on WOODCARB II
27 landfill decay rates.

28 **Recalculations Discussion**

29 Forest ecosystem stock and stock-change estimates differ from previous Inventory reports in two primary ways.
30 First, a different estimation system was used in this Inventory and the previous (1990 to 2014) Inventory (Woodall
31 et al. 2015a). The major differences between the estimation system used in the last two Inventory reports and past
32 estimation approaches is the sole use of annual FIA data and the back-casting of forest C stocks across the 1990s
33 based on forest C stock density and land use change information obtained from the nationally consistent annual
34 forest inventory coupled with in situ observations of non-tree C pools such as soils, dead wood, and litter in the
35 1990-2014 Inventory and this Inventory. The use of this estimation framework has enabled the creation of the two
36 land use sections for forest C stocks: *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*. In
37 prior Inventory reports (e.g., the 1990 to 2013 Inventory), the C stock changes from *Land Converted to Forest Land*
38 were a part of the *Forest Land Remaining Forest Land* section and it was not possible to disaggregate the estimates
39 with the methodology applied at that time. A second major change in the 1990-2014 Inventory submission was the
40 adoption of a new approach to estimate forest soil C, the largest C stock in the United States. However, the litter and
41 soil C stock and stock change estimates reported in the 1990 to 2014 Inventory were inadvertently compiled using
42 English units resulting in estimates that were 2.2 times larger than they should have been for the *Forest Land*
43 *Remaining Forest Land* category. This mistake was not caught during compilation of the previous Inventory report
44 since the soil C model and the estimation system used to compile estimates for the United States were both being
45 used for the first time with no similar (e.g., national-level population estimates using similar data) estimates
46 available for comparison. In addition to these major changes, the refined land representation analysis described in
47 Section 6.1 *Representation of the U.S. Land Base* re-classified some of the forest land in south central and
48 southeastern coastal Alaska as unmanaged; this is in contrast to past assumptions where forest lands included in the
49 FIA database were always considered part of the “managed” land base. Therefore, the C stock and flux estimates for
50 southeast and south central coastal Alaska, as included here, reflect that adjustment, which effectively reduces the
51 managed forest area by approximately 5 percent.

52 In addition to the creation of explicit estimates of removals and emissions from *Forest Land Remaining Forest Land*
53 and *Land Converted to Forest Land*, the estimation system used in the current Inventory and the previous (1990 to

1 2014) Inventory eliminated the use of periodic data (which may be inconsistent with annual inventory data) and
2 contributed to a data artifact in prior estimates of emissions/removals from 1990 to the present. In the previous
3 Inventory reports (i.e., prior to the 1990 to 2014 Inventory), there was a reduction in net sequestration from 1995 to
4 2000 followed by an increase in net sequestration from 2000 to 2004. This artifact, resulting from comparing
5 inconsistent inventories of the 1980s through 1990s to the nationally consistent inventories of the 2000s has been
6 removed in the last two Inventory reports.

7 Emissions from drained organic soil within *Forest Land Remaining Forest Land* and *Land Converted to Forest*
8 *Land* are reported for the first time in this Inventory. These estimates of drained organic soils on forest land are
9 identified separately from other forest soils largely because mineralization of the exposed or partially dried organic
10 material results in continuous CO₂ emissions (IPCC 2006). This distinction merits the separate estimates provided
11 here according to IPCC (2006) and primarily the *2013 Supplement to the 2006 IPCC Guidelines for National*
12 *Greenhouse Gas Inventories: Wetlands* (IPCC 2013).

13 Estimated annual net additions to HWP C stocks increased slightly between 2014 and 2015 but decreased overall
14 dating back to 2008 due to revised data for the solidwood products in use category. The decline in net additions to
15 HWP C stocks continued through 2009 from the recent high point in 2006. This is due to sharp declines in U.S.
16 production of solidwood and paper products in 2007 and 2008 primarily due to the decline in housing construction.
17 The low level of gross additions to solidwood and paper products in use in 2009 and 2010 were exceeded by
18 discards from uses. The result is a net reduction in the amount of HWP C that is held in products in use during this
19 time period and ultimately this category became a net source. Since the recent recession in 2009 the products in use
20 have not recovered while additions to the SWDS have remained relatively stable.

21 **Planned Improvements**

22 Reliable estimates of forest C stocks and changes across the diverse ecosystems of the U.S. require a high level of
23 investment in both annual monitoring and associated analytical techniques. Development of improved
24 monitoring/reporting techniques is a continuous process that occurs simultaneously with annual Inventory
25 submissions. Planned improvements can be broadly assigned to the following categories: development of a robust
26 estimation and reporting system, individual C pool estimation, coordination with other land-use categories, and
27 annual inventory data incorporation.

28 As this is only the second Inventory submission to delineate C change by *Forest Land Remaining Forest Land* and
29 *Land Converted to Forest Land*, there are many improvements that are still necessary. Since the estimation approach
30 used this year operates at the regional scale for the U.S., research is underway to leverage auxiliary information (i.e.,
31 remotely sensed information) to operate at finer spatial scales. As in past submissions, deforestation is implicitly
32 included in the report given the design of the annual forest inventory system, but not explicitly estimated. The
33 transparency and repeatability of estimation and reporting systems will be improved through the dissemination of
34 open source code (e.g., R programming language) in concert with the public availability of the annual forest
35 inventory data (USDA Forest Service 2016b). Also, several FIA database processes are being institutionalized to
36 increase efficiency and QA/QC in reporting and further improve transparency, completeness, consistency, accuracy,
37 and availability of data used in reporting. Finally, a Tier 1 approach was used to estimate uncertainty associated with
38 C stock changes in the *Forest Land Remaining Forest Land* category in this report. There is research underway
39 investigating more robust approaches to total uncertainty (Clough et al. 2016) which will be considered in future
40 Inventory reports.

41 The modeling framework used to estimate downed dead wood within the dead wood C pool will be updated similar
42 to the litter (Domke et al. 2016) and soil C pools (Domke et al. In press). Finally, components of other pools, such as
43 C in belowground biomass (Russell et al. 2015) and understory vegetation (Russell et al. 2014; Johnson et al. In
44 review), are being explored but may require additional investment in field inventories before improvements can be
45 realized with Inventory submissions.

46 The foundation of forest C estimation and reporting is the annual forest inventory system. The ongoing annual
47 surveys by the FIA program are expected to improve the accuracy and precision of forest C estimates as new state
48 surveys become available (USDA Forest Service 2016b), particularly in western states. Hawaii and U.S. Territories
49 will be included when appropriate forest C data are available (as of April 30, 2016, only a small number of plots
50 from Hawaii were available from the annualized sampling design). Forest lands in interior Alaska are now included
51 in the annual forest inventory, however alternative methods of estimating C stock change will need to be explored as

1 it will take several years to re-measure newly established plots. To that end, research is underway to incorporate all
 2 FIA plot information (both annual and periodic data) and the dense time-series of remotely sensed data in a design-
 3 based, model-assisted format for estimating greenhouse gas emissions and removals as well as change detection and
 4 attribution across the entire reporting period and all managed forest land in the U.S. Leveraging this auxiliary
 5 information will aid not only the interior Alaska effort but the entire inventory system. In addition to fully
 6 inventorying all managed forest land in the U.S., the more intensive sampling of fine woody debris, litter, and SOC
 7 on a subset of FIA plots continues and will substantially improve resolution of C pools (i.e., greater sample
 8 intensity; Westfall et al. 2013) as this information becomes available (Woodall et al. 2011b). Increased sample
 9 intensity of some C pools and using annualized sampling data as it becomes available for those states currently not
 10 reporting are planned for future submissions. The FIA sampling frame extends beyond the forest land use category
 11 (e.g., woodlands and urban areas) with inventory-relevant information for these lands which will likely become
 12 increasingly available in coming years.

Box 6-4: Preliminary Estimates of Historical Carbon Stock Change and Methane Emissions from Managed Land in Alaska (Represents Mean for Years 2000 to 2009)

15 Starting in the 1990s, a forest inventory of south central and southeastern coastal (SCSE) Alaska was initiated
 16 following the same approach applied in the conterminous U.S. These data have been used to compile Forest Land
 17 estimates for SCSE Alaska in the U.S. Inventory since 2008. However, there still remain vast expanses of Alaska
 18 that are in the U.S. managed land base (See Section 0) where forest inventories have only recently been established
 19 and thus are not included as part of the greenhouse gas flux reporting in this Inventory. In addition, this Inventory
 20 does not report on Grasslands in Alaska due to lack of land use and management data. Recognizing the need to
 21 report on these emissions and removals, efforts have been initiated to apply a combination of approaches that will
 22 eventually lead to complete reporting for all managed land in Alaska. The most promising near-term option for
 23 Forest Lands that would meet the minimum UNFCCC reporting requirements is application of the IPCC Tier 1
 24 Gain-Loss Method. Work is also underway to utilize forest inventory plots in combination with remote sensing to
 25 estimate C stock changes. This work was initiated as a pilot study and has now moved fully operational with the
 26 annual forest inventory in interior Alaska underway. Full implementation of either of these approaches for reporting
 27 in the Inventory is several years in the future.

28 In order to provide some insight into the greenhouse gas flux in Alaska, preliminary C stock change and CH₄
 29 emissions for Alaska have been developed using data from a recently completed USGS effort overlaid on the
 30 Alaskan managed land base to provide a preliminary assessment of the mean historical anthropogenic greenhouse
 31 gas flux between 2000 and 2009.

32 The assessment by the USGS, in collaboration with USDA Forest Service and the University of Alaska in Fairbanks,
 33 estimated Alaska C stock changes and CH₄ emissions using an approach that couples modeling, remote sensing
 34 analysis, literature and database review (Zhu and McGuire, eds, 2016). Annual variation of soil and vegetation C
 35 stocks and associated CO₂ and CH₄ fluxes, in both upland and wetland ecosystems in Alaska, were analyzed from
 36 1950 to 2009, using this USGS modeling framework.

37 Results of the assessment include C stocks and fluxes from vegetation and soil organic C pools, and CH₄ fluxes.
 38 Vegetation C pools included aboveground and belowground biomass. The soil C pool included dead woody debris
 39 and C stored in organic and mineral horizons. Carbon dioxide fluxes from vegetation net primary productivity, soil
 40 heterotrophic respiration, wildfire emissions and harvest were estimated. Methane fluxes included biogenic and
 41 pyrogenic sources. The results of this USGS analysis (i.e., mean values for 2000 to 2009-time period) overlaid on
 42 the Alaskan managed land base are presented in Table 6-15.

Table 6-15: Mean C Stocks, CO₂ and CH₄ Fluxes in Alaska between 2000 and 2009

Land Use: C Pool	Area (1,000 ha) ^a	C stock (MMT C)	CO ₂ Flux (Change in C stocks) (MMT CO ₂ Eq./Year) ^b	CH ₄ Flux (MMT CO ₂ Eq./Year)
Forest Land	39,917	15,226	44.86	1.675
Aboveground Biomass	-	2,130	4.03	-
Belowground Biomass	-	532		-
Soil ^c	-	12,563	40.83	
Grassland^d	34,844	18,856	(30.60)	0.102

Aboveground Vegetation	-	315	(5.83)	-
Belowground Vegetation	-	178		-
Soil ^c	-	18,363	(24.77)	-
Wetland	12,346	3,927	17.52	23,170
Aboveground Vegetation	-	264	1.12	-
Belowground Vegetation	-	176		-
Soil ^c	-	3,487	16.41	-
Total	87,107	38,008	31.80	24,947

^a The USGS assessment did not include the Aleutian Islands, Saint Lawrence Island, glacier, bare ground or urban areas, therefore the area data does not match up precisely with the Land Representation analysis in this Inventory (see Section 6.1 for more details).

^b This assessment considers carbon exported out of the ecosystem from harvesting as a loss, it does not include the contribution to the harvested wood products pool.

^c Soil pool includes dead woody debris and C stored in organic and mineral horizons.

^d Grassland also includes heath and shrubland

Note: Parentheses indicate net sequestration.

1

2 Non-CO₂ Emissions from Forest Fires

3 Emissions of non-CO₂ gases from forest fires were estimated using U.S.-specific data for annual area of forest
 4 burned and potential fuel availability as well as the default IPCC (2006) emissions and combustion factors applied to
 5 the IPCC methodology. In 2015, emissions from this source were estimated to be 7.3 MMT CO₂ Eq. of CH₄ and 4.8
 6 MMT CO₂ Eq. of N₂O (Table 6-16; kt units provided in Table 6-17). The estimates of non-CO₂ emissions from
 7 forest fires include wildfires and prescribed fires in the conterminous 48 states and Alaska.

8 **Table 6-16: Non-CO₂ Emissions from Forest Fires (MMT CO₂ Eq.)^a**

Gas	1990	2005	2011	2012	2013	2014	2015 ^b
CH ₄	3.2	9.4	6.8	10.8	7.2	7.3	7.3
N ₂ O	2.1	6.2	4.5	7.1	4.7	4.8	4.8
Total	5.3	15.6	11.3	17.9	11.9	12.1	12.1

^a These estimates include Non-CO₂ Emissions from Forest Fires on *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*.

^b The data for 2015 were incomplete when these estimates were developed, therefore 2014, the most recent available estimate, is applied to 2015.

9 **Table 6-17: Non-CO₂ Emissions from Forest Fires (kt)^a**

Gas	1990	2005	2011	2012	2013	2014	2015 ^b
CH ₄	128	378	273	431	289	292	292
N ₂ O	7	21	15	24	16	16	16
CO	2,832	8,486	6,136	9,815	6,655	6,642	6,642
NO _x	80	239	172	276	185	188	188

^a These estimates include Non-CO₂ Emissions from Forest Fires on *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*.

^b The data for 2015 were incomplete when these estimates were summarized, therefore 2014, the most recent available estimate, is applied to 2015.

1 Methodology

2 Non-CO₂ emissions from forest fires—primarily CH₄ and N₂O emissions—were calculated following IPCC (2006)
3 methodology, which included a combination of U.S. specific data on area burned and potential fuel available for
4 combustion along with IPCC default combustion and emission factors. The estimates were calculated according to
5 Equation 2.27 of IPCC (2006, Volume 4, Chapter 2), which is:

$$6 \quad \text{Emissions} = \text{Area burned} \times \text{Fuel available} \times \text{Combustion factor} \times \text{Emission factor} \times 10^{-3}$$

7 where area burned data are based on Monitoring Trends in Burn Severity (MTBS) data summaries (MTBS 2015),
8 fuel estimates are based on current C density estimates obtained from the latest FIA data for each state, and
9 combustion and emission factors are from IPCC (2006, Volume 4, Chapter 2). See Annex 3.13 for further details.

10 Uncertainty and Time-Series Consistency

11 In order to quantify the uncertainties for non-CO₂ emissions from wildfires and prescribed burns, a Monte Carlo
12 (IPCC Approach 2) sampling approach was employed to propagate uncertainty based on the model and data applied
13 for U.S. forest land. See IPCC (2006) and Annex 3.13 for the quantities and assumptions employed to define and
14 propagate uncertainty. The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 6-18.

15 **Table 6-18: Quantitative Uncertainty Estimates of Non-CO₂ Emissions from Forest Fires**
16 **(MMT CO₂ Eq. and Percent)^a**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^b			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Non-CO ₂ Emissions from Forest Fires	CH ₄	7.3	2.7	19.1	-63%	161%
Non-CO ₂ Emissions from Forest Fires	N ₂ O	4.8	1.9	12.3	-60%	157%

^a These estimates include Non-CO₂ Emissions from Forest Fires on *Forest Land Remaining Forest Land* and *Land
Converted to Forest Land*.

^b Range of flux estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

17 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
18 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
19 above.

20 QA/QC and Verification

21 Tier 1 and Tier 2 QA/QC activities were conducted consistent with the U.S. QA/QC plan. Source-specific quality
22 control measures for forest fires included checking input data, documentation, and calculations to ensure data were
23 properly handled through the inventory process. Further, the set of fire emissions estimates using MODIS imagery
24 and post-fire observations developed for Alaska by Veraverbeke et al. (2015) (Annex 3.13, Table A-247 were
25 compared to the estimates of CO₂ and C emissions from forest fires in Alaska (Table 6-13 and Annex 3.13 Table A-
26 248). These alternate sources of data for annual areas burned and possible fuel availability in Alaska were found to
27 be similar to the data used here. The QA/QC procedures did not reveal any inaccuracies or incorrect input values.

28 Recalculations Discussion

29 The current non-CO₂ emissions estimates are based on the calculation described above and in IPCC (2006), which is
30 a very similar approach to the basic calculation of previous Inventory reports. However, some of the data
31 summarized and applied to the calculations are very different for the current Inventory. The use of the MTBS data
32 summaries is the most prominent example. Annual burned areas on managed forest lands were identified according
33 to Ruefenacht et al. (2008) and Ogle et al. (In preparation). The other change with the estimates provided in this
34 Inventory is in the use of the underlying plot level C densities based on forest inventory plots. Although the base

1 data are similar to past years, the current uncertainty estimates are based on an assumption that plot-to-plot
 2 variability is a greater influence on uncertainty than the uncertainty in the forest-inventory to C conversion factors
 3 (as employed for uncertainty in the past). See Annex 3.13 for additional details.

4 **Planned Improvements**

5 Possible future improvements within the context of this same IPCC (2006) methodology are most likely to involve
 6 greater specificity by fire or groups of fires and less reliance on wide regional values or IPCC defaults. Spatially
 7 relating potential fuel availability to more localized forest structure is the best example of this. An additional
 8 improvement would be the use of combustion factors that are more locally appropriate for the type, location, and
 9 intensity of fire, which are currently unused information provided with the MTBS data summaries. All planned
 10 improvements depend on future availability of appropriate U.S.-specific data.

11 **N₂O Emissions from N Additions to Forest Soils**

12 Anthropogenic management can influence the N cycles in several ways and lead to higher N₂O emissions, such as
 13 fertilization, planting N-fixing species, and drainage of organic soils. This Inventory addresses the impact of N
 14 fertilization management on soil N₂O emissions, but may be extended to include other management impacts in
 15 future inventories. Of the synthetic nitrogen (N) fertilizers applied to soils in the U.S., no more than one percent is
 16 applied to forest soils and most of those additions occur in the industrial forests of the southeastern U.S. Application
 17 rates are similar to those occurring on cropland soils, but in any given year, only a small proportion of total forested
 18 land receives N fertilizer. This is because forests are typically fertilized only twice during their approximately 40-
 19 year growth cycle (once at planting and once midway through their life cycle). While the rate of N fertilizer
 20 application for the area of forests that receives N fertilizer in any given year is relatively high, the annual application
 21 rate is quite low over the entire forestland area.

22 N additions to forest soils result in direct and indirect N₂O emissions. Direct emissions occur on-site due to the N
 23 additions. Indirect emissions result from fertilizer N that is transformed and transported to another location in a form
 24 other than N₂O (i.e., ammonia [NH₃] and nitrogen oxide [NO_x] through volatilization, and nitrate [NO₃⁻] through
 25 leaching and runoff), and later converted into N₂O at the off-site location. These indirect emissions are assigned to
 26 forest land because the management activity leading to the emissions occurred on forest land.

27 Direct soil N₂O emissions from *Forest Land Remaining Forest Land* and *Land Converted to Forest Land* in 2015
 28 were 0.3 MMT CO₂ Eq. (1 kt), and the indirect emissions were 0.1 MMT CO₂ Eq. (0.4 kt). Total emissions for 2015
 29 were 0.5 MMT CO₂ Eq. (2 kt) and have increased by 455 percent from 1990 to 2015. Increasing emissions over the
 30 time series is a result of an increasing area of N fertilized pine plantations in the southeastern U.S. and Douglas-fir
 31 timberland in western Washington and Oregon. Total forest soil N₂O emissions are summarized in Table 6-19.

32 **Table 6-19: N₂O Emissions from N Additions to Soils^{a, b} (MMT CO₂ Eq. and kt N₂O)**

	1990	2005	2011	2012	2013	2014	2015
Direct N₂O Fluxes from Forest Soils							
MMT CO ₂ Eq.	0.1	0.3	0.3	0.3	0.3	0.3	0.3
kt N ₂ O	+	1	1	1	1	1	1
Indirect N₂O Fluxes from Forest Soils							
MMT CO ₂ Eq.	0.0	0.1	0.1	0.1	0.1	0.1	0.1
kt N ₂ O	+	+	+	+	+	+	+
Total							
MMT CO ₂ Eq.	0.1	0.5	0.5	0.5	0.5	0.5	0.5
kt N ₂ O	+	2	2	2	2	2	2

+ Does not exceed 0.05 MMT CO₂ Eq. or 0.5 kt.

^a This table includes estimates from *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*

^b N₂O from drained organic soils from *Forest Land Remaining Forest Land* and *Land Converted to Forest Land* are reported in that subsection in this inventory.

Note: Totals may not sum due to independent rounding.

1 **Methodology**

2 The IPCC Tier 1 approach is used to estimate N₂O emissions from soils within *Forest Land Remaining Forest Land*
3 and *Land Converted to Forest Land*. According to U.S. Forest Service statistics for 1996 (USDA Forest Service
4 2001), approximately 75 percent of trees planted are for timber, and about 60 percent of national total harvested
5 forest area is in the southeastern U.S. Although southeastern pine plantations represent the majority of fertilized
6 forests in the U.S., this Inventory also accounts for N fertilizer application to commercial Douglas-fir stands in
7 western Oregon and Washington. For the Southeast, estimates of direct and indirect N₂O emissions from fertilizer
8 applications to forests are based on the area of pine plantations receiving fertilizer in the southeastern U.S and
9 estimated application rates (Albaugh et al. 2007; Fox et al. 2007). Not accounting for fertilizer applied to non-pine
10 plantations is justified because fertilization is routine for pine forests but rare for hardwoods (Binkley et al. 1995).
11 For each year, the area of pine receiving N fertilizer is multiplied by the weighted average of the reported range of N
12 fertilization rates (121 lbs. N per acre). Area data for pine plantations receiving fertilizer in the Southeast are not
13 available for 2005 through 2015, so data from 2004 are used for these years. For commercial forests in Oregon and
14 Washington, only fertilizer applied to Douglas-fir is addressed in this Inventory because the vast majority
15 (approximately 95 percent) of the total fertilizer applied to forests in this region is applied to Douglas-fir (Briggs
16 2007). Estimates of total Douglas-fir area and the portion of fertilized area are multiplied to obtain annual area
17 estimates of fertilized Douglas-fir stands. Similar to the Southeast, data are not available for 2005 through 2015, so
18 data from 2004 are used for these years. The annual area estimates are multiplied by the typical rate used in this
19 region (200 lbs. N per acre) to estimate total N applied (Briggs 2007), and the total N applied to forests is multiplied
20 by the IPCC (2006) default emission factor of one percent to estimate direct N₂O emissions.

21 For indirect emissions, the volatilization and leaching/runoff N fractions for forest land are calculated by
22 multiplying the amount of fertilizer by the IPCC default factors of 10 percent and 30 percent, respectively as well as
23 from the quantities of fertilizer describes above for direct emissions. The amount of N volatilized is multiplied by
24 the IPCC default factor of one percent for the portion of volatilized N that is converted to N₂O off-site. The amount
25 of N leached/runoff is multiplied by the IPCC default factor of 0.075 percent for the portion of leached/runoff N that
26 is converted to N₂O off-site. The resulting estimates are summed to obtain total indirect emissions.

27 **Uncertainty and Time-Series Consistency**

28 The amount of N₂O emitted from forests depends not only on N inputs and fertilized area, but also on a large
29 number of variables, including organic C availability, oxygen gas partial pressure, soil moisture content, pH,
30 temperature, and tree planting/harvesting cycles. The effect of the combined interaction of these variables on N₂O
31 flux is complex and highly uncertain. IPCC (2006) does not incorporate any of these variables into the default
32 methodology, except variation in estimated fertilizer application rates and estimated areas of forested land receiving
33 N fertilizer. All forest soils are treated equivalently under this methodology. Furthermore, only synthetic N
34 fertilizers are captured, so applications of organic N fertilizers or other possible N addition, as mentioned above, are
35 not estimated, as well as other anthropogenic impacts on the N cycle such as drainage of organic soils. However, the
36 total quantity of organic N inputs to soils is included in Section 5.4 *Agricultural Soil Management* and Section 6.10
37 *Settlements Remaining Settlements*.

38 Uncertainties exist in the fertilization rates, annual area of forest lands receiving fertilizer, and the emission factors.
39 Fertilization rates are assigned a default level³⁰ of uncertainty at ±50 percent, and area receiving fertilizer is
40 assigned a ±20 percent according to expert knowledge (Binkley 2004). The uncertainty ranges around the 2005
41 activity data and emission factor input variables are directly applied to the 2015 emission estimates. IPCC (2006)
42 provided estimates for the uncertainty associated with direct and indirect N₂O emission factor for synthetic N
43 fertilizer application to soils.

44 Uncertainty is quantified using simple error propagation methods (IPCC 2006). The results of the quantitative
45 uncertainty analysis are summarized in Table 6-20. Direct N₂O fluxes from soils in 2015 are estimated to be
46 between 0.1 and 1.1 MMT CO₂ Eq. at a 95 percent confidence level. This indicates a range of 59 percent below and
47 211 percent above the 2015 emission estimate of 0.3 MMT CO₂ Eq. Indirect N₂O emissions in 2015 are between

³⁰ Uncertainty is unknown for the fertilization rates so a conservative value of ±50 percent is used in the analysis.

1 0.02 and 0.4 MMT CO₂ Eq., ranging from 86 percent below to 238 percent above the 2015 emission estimate of 0.1
 2 MMT CO₂ Eq.

3 **Table 6-20: Quantitative Uncertainty Estimates of N₂O Fluxes from Soils in *Forest Land***
 4 ***Remaining Forest Land and Land Converted to Forest Land (MMT CO₂ Eq. and Percent)***

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate (MMT CO ₂ Eq.)			
			Lower Bound		Upper Bound	
Forest Land Remaining Forest Land						
Direct N ₂ O Fluxes from Soils	N ₂ O	0.3	0.1	1.1	-59%	211%
Indirect N ₂ O Fluxes from Soils	N ₂ O	0.1	+	0.4	-86%	238%

+ Does not exceed 0.05 MMT CO₂ Eq.

5 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 6 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 7 above.

8 QA/QC and Verification

9 The spreadsheet tab containing N fertilizer applied to forests and calculations for N₂O and uncertainty ranges are
 10 checked and verified.

11 Planned Improvements

12 Additional data will be compiled to update estimates of forest areas receiving N fertilizer as new reports are made
 13 available. Another improvement is to further disaggregate emissions by state for southeastern pine plantations and
 14 northwestern Douglas-fir forests to estimate soil N₂O emission. This improvement is contingent on the availability
 15 of state-level N fertilization data for forest land.

16 Drained Organic Soils

17 *Emissions from drained organic soils on forest land are reported in the Inventory for the first time. While the*
 18 *Inventory text includes drained organic soils, the net greenhouse gas emissions total and LULUCF sector total*
 19 *presented in this Inventory do not include emissions from drained organic soils. Emissions from drained organic*
 20 *soils will be included in net emissions and LULUCF totals in the final 1990 to 2015 Inventory report.*

21 Drained organic soils on forest land are identified separately from other forest soils largely because mineralization
 22 of the exposed or partially dried organic material results in continuous CO₂ and N₂O emissions (IPCC 2006). This
 23 distinction merits the separate estimates provided here according to IPCC (2006) and primarily the new guidance in
 24 the *2013 Supplement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories: Wetlands* (IPCC
 25 2014).

26 Organic soils are identified on the basis of thickness of organic horizon and percent organic matter. All organic soils
 27 are assumed to have originally been wet, and drained organic soils are further characterized by drainage or the
 28 process of artificially lowering the soil water table, which exposes the organic material to drying and the associated
 29 emissions described in this section. The land base considered here is drained inland organic soils that are coincident
 30 with forest area as identified by the forest inventory of the USDA Forest Service (USDA Forest Service 2016).

31 The estimated area of drained organic soils on forest land is 70,849 ha and did not change over the time series based
 32 on the data used to compile the estimates in this Inventory. These estimates are based on permanent plot locations of
 33 the forest inventory (USDA Forest Service 2016) coincident with mapped organic soil locations (STATSGO2 2016),
 34 which identifies forest land on organic soils. Forest sites that are drained are not explicitly identified in the data, but

1 for this estimate, planted forest stands on sites identified as mesic or xeric (which are identified in USDA Forest
 2 Service 2016) are labeled “drained organic soil” sites.

3 Land use, region, and climate are broad determinants of emissions as are more site specific factors such as nutrient
 4 status, drainage level, exposure, or disturbance. Current data are limited in spatial precision and thus lack site
 5 specific details. At the same time, corresponding emissions factor data specific to U.S. forests are similarly lacking.
 6 Tier 1 estimates are provided here following IPCC (2014). Total annual emissions on forest land with drained
 7 organic soils in 2015 are estimated as 0.9 MMT CO₂ Eq. per year (Table 6-21) with uncertainty (as the 95 percent
 8 confidence interval) at 38 percent (Table 6-24).

9 The Tier 1 methodology provides methods to estimate C emission as CO₂ from three pathways: direct emissions
 10 primarily from mineralization; indirect, or off-site, emissions associated with dissolved organic carbon releasing
 11 CO₂ from drainage waters; and emissions from (peat) fires on organic soils. Data about forest fires specifically
 12 located on drained organic soils are not currently available; as a result, no corresponding estimate is provided here.
 13 Non-CO₂ emissions provided here include CH₄ and N₂O. Methane emissions generally associated with anoxic
 14 conditions do occur from the drained land surface but the majority of these emissions originate from ditches
 15 constructed to facilitate drainage at these sites. Emission of N₂O can be significant from these drained organic soils
 16 in contrast to the very low emissions from wet organic soils.

21 Methodology

22 The Tier 1 methods for estimating emissions from drained inland organic soils on forest lands follow IPCC (2006),
 23 with extensive updates and additional material presented in the *2013 Supplement to the 2006 IPCC Guidelines for*
 24 *National Greenhouse Gas Inventories: Wetlands* (IPCC 2014). With the exception of quantifying area of forest on
 25 drained organic soils, which is user-supplied, all quantities necessary for Tier 1 estimates are provided in Chapter 2,
 26 *Drained Inland Organic Soils of IPCC (2014)*.

27 Estimated area of drained organic soils on forest land is 70,849 ha based on analysis of the permanent forest
 28 inventory of the USDA Forest Service and did not change over the time series (2016, data downloaded 14 June
 29 2016). The current (i.e., most-recent) plot data per state were used in a spatial overlay with the STATSGO2 (2016)
 30 data, and forest plots coincident with the soil order histosol were selected as having organic soils. Information

1 specific to identifying “drained organic” are not in the inventory data so an indirect approach was employed here.
 2 Specifically, artificially regenerated forest stands (inventory field STDORGCD=1) on mesic or xeric sites (inventory
 3 field 11≤PHYSCLCD≤29) are labeled “drained organic soil” sites. From this selection, forest area and sampling
 4 error for forest on drained organic sites are based on the population estimates developed within the inventory data
 5 for each state (USDA Forest Service 2016). Eight states, all temperate forests, were identified as having drained
 6 organic soils (Table 6-23).

7 **Table 6-23: States identified as having Drained Organic Soils, Area of Forest on Drained**
 8 **Organic Soils, and Sampling Error**

State	Forest on Drained Organic Soil (1,000 ha)	Sampling Error (68.3% as ± Percentage of Estimate)
Florida	2.4	79
Georgia	3.7	71
Michigan	18.7	34
Minnesota	30.2	19
North Carolina	1.3	99
Virginia	2.3	102
Washington	2.1	101
Wisconsin	10.1	30
Total	70.8	14

9
 10 The Tier 1 methodology provides methods to estimate emissions for three pathways of C emission as CO₂ (Table
 11 6-21 and Table 6-22). Note that subsequent mention of equations and tables in the remainder of this section refer to
 12 Chapter 2 of IPCC 2014. The first pathway—direct CO₂ emissions—is calculated according to Equation 2.3 and Table
 13 2.1 as the product of forest area and emission factor for temperate drained forest land. The second pathway—indirect,
 14 or off-site, emissions—is associated with dissolved organic carbon releasing CO₂ from drainage waters according to
 15 Equation 2.4 and Table 2.2, which represent a default composite of the three pathways for this flux: (1) the flux of
 16 dissolved organic carbon (DOC) from natural (undrained) organic soil; (2) the proportional increase in DOC flux
 17 from drained organic soils relative to undrained sites; and (3) the conversion factor for the part of DOC converted to
 18 CO₂ after export from a site. The third pathway – emissions from (peat) fires on organic soils—assumes that the
 19 drained organic soils burn in a fire but not any wet organic soils. However, we do not include emissions for this
 20 pathway because we do not have the combined fire and drained organic soils information; this may become
 21 available in the future with additional analysis.

22 Non-CO₂ emissions, according to the Tier 1 method, include methane (CH₄), nitrous oxide (N₂O), and carbon
 23 monoxide (CO) (Table 6-16). Emissions associated with peat fires include factors for CH₄ and CO in addition to
 24 CO₂, but fire estimates are assumed to be zero for this inventory, as discussed above. Methane emissions generally
 25 associated with anoxic conditions do occur from the drained land surface but the majority of these emissions
 26 originate from ditches constructed to facilitate drainage at these sites. From this, two separate emission factors are
 27 used, one for emissions from the area of drained soils and a second for emissions from drainage ditch waterways.
 28 Calculations are according to Equation 2.6 and Tables 2.3 and 2.4, which includes the default fraction of the total
 29 area of drained organic soil which is occupied by ditches. Emission of nitrous oxide can be significant from these
 30 drained soils in contrast to the very low emissions from wet organic soils. Calculations are according to Equation 2.7
 31 and Table 2.5, which provide the estimate as kg N per year.

32 **Uncertainty and Time-Series Consistency**

33 Uncertainties are based on the sampling error associated with forest area and the uncertainties provided in the
 34 Chapter 2 (IPCC 2014) emissions factors (Table 6-24). The estimates and resulting quantities representing
 35 uncertainty are based on the Approach 1 – error propagation. However, probabilistic sampling of the distributions
 36 defined for each emission factor produced a histogram result that contained a mean and 95 percent confidence
 37 interval. The primary reason for this approach was to develop a numerical representation of uncertainty with the
 38 potential for combining with other forest components. The total emissions in 2015 from drained organic soils on

1 *Forest Land Remaining Forest Land* and *Land Converted to Forest Land* were estimated to be between 0.5 and 1.2
 2 MMT CO₂ Eq. around a central estimate of 0.9 MMT CO₂ Eq. at a 95 percent confidence level.

3 **Table 6-24: Quantitative Uncertainty Estimates for Annual CO₂ and Non-CO₂ Emissions on**
 4 **Drained Organic Forest Soils (MMT CO₂ Eq. and Percent)^a**

Source	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate			
		(MMT CO ₂ Eq.)		(%)	
	Lower Bound	Upper Bound	Lower Bound	Upper Bound	
CO ₂ , direct	0.7	0.4	0.9	-39%	39%
CO ₂ , dissolved organic C	0.1	+	0.1	-56%	56%
CH ₄	+	+	+	-76%	76%
N ₂ O	0.1	+	0.2	-124%	124%
Total	0.9	0.5	1.2	-38%	38%

+ Does not exceed 0.05 MMT CO₂ Eq.

^aRange of flux estimates predicted through a combination of sample based and IPCC defaults for a 95 percent confidence interval, IPCC Approach 1.

5 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 6 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 7 above.

8 QA/QC and Verification

9 IPCC (2014) guidance cautions of a possibility of double counting some of these emissions. Specifically, the off-site
 10 emissions of dissolved organic C from drainage waters may be double counted if soil C stock and change is based
 11 on sampling and this C is captured in that sampling. Additionally, some of the non-CO₂ emissions maybe be
 12 included in either the Wetlands or sections on N₂O emissions from managed soils. These paths to double counting
 13 emissions are unlikely here because these issues are taken into consideration when developing the estimates and this
 14 chapter is the only section directly including such emissions on forest land.

15 Planned Improvements

16 Additional data will be compiled to update estimates of forest areas on drained organic soils as new reports are made
 17 available and new geospatial products become available.

18 6.3 Land Converted to Forest Land (IPCC 19 Source Category 4A2)

20 The C stock change estimates for *Land Converted to Forest Land* that are provided in this Inventory include all
 21 forest land in an inventory year that had been in another land use(s) during the previous 20 years³¹ (USDA NRCS
 22 2012). For example, cropland or grassland converted to forest land during the past 20 years would be reported in this
 23 category. Converted lands are in this category for 20 years as recommended in the *2006 IPCC Guidelines* (IPCC
 24 2006), after which they are classified as *Forest Land Remaining Forest Land*. Estimates of C stock changes from
 25 mineral soils are included in *Land Converted to Forest Land* following Ogle et al (2003, 2006) and IPCC (2006).
 26 Carbon stock changes for the other pools (i.e., aboveground and belowground biomass, dead wood, and litter), as

³¹ The 2009 USDA National Resources Inventory (NRI) land-use survey points were classified according to land-use history records starting in 1982 when the NRI survey began. Consequently, the classifications from 1990 to 2001 were based on less than 20 years. Furthermore, the FIA data used to compile estimates of carbon sequestration in this section are based on 5- to 10-yr remeasurements so the exact conversion period was limited to the remeasured data over the time series.

1 recommended for inclusion by IPCC (2006) are included for the *Land Converted to Forest Land* category for the
 2 first time in this Inventory.

3 *Area of Land Converted to Forest in the United States*

4 Land conversion to and from forests has occurred regularly throughout U.S. history. The 1970s and 1980s saw a
 5 resurgence of federally-sponsored forest management programs (e.g., the Forestry Incentive Program) and soil
 6 conservation programs (e.g., the Conservation Reserve Program), which have focused on tree planting, improving
 7 timber management activities, combating soil erosion, and converting marginal cropland to forests. Recent analyses
 8 suggest that net accumulation of forest area continues in areas of the U.S., in particular the northeastern U.S.
 9 (Woodall et al. 2015b). Specifically, the annual conversion of land from other land-use categories (i.e., Cropland,
 10 Grassland, Wetlands, Settlements, and Other Lands) to Forest Land resulted in a fairly continuous net annual
 11 accretion of Forest Land area from 1990 to the present at an average rate of 1 million ha year⁻¹.

12 Since 1990, the conversion of grassland to forest land resulted in the largest source of C sequestration, accounting
 13 for approximately 67 percent of the sequestration in the *Land Converted to Forest Land* category in 2015. However,
 14 estimated gains have decreased over the time series due to less Grassland conversion into the Forest Land category
 15 in recent years (see Table 6-25). The net flux of C from all forest pool stock changes in 2015 was -75.2 MMT CO₂
 16 Eq. (-20.5 MMT C) (Table 6-25 and Table 6-26). Note that soil C in this Inventory report has historically been
 17 reported to a depth of 100 cm in the *Forest Land Remaining Forest Land* category (Domke et al. In press) while
 18 other land-use categories report soil C to a depth of 20 or 30 cm. To ensure consistency in the *Land Converted to*
 19 *Forest Land* category where C stock transfers occur between land-use categories, all soil C estimates are based on
 20 methods from Ogle et al. (2003, 2006) and IPCC (2006), which are also used in Cropland, Grasslands and
 21 Settlements land use categories of this Inventory.

4 Methodology

5 The following section includes a description of the methodology used to estimate stock changes in all forest C pools
6 for *Land Converted to Forest Land*. Forest Inventory and Analysis data and IPCC (2006) defaults for reference C
7 stocks were used to compile separate estimates for the five C storage pools. Estimates for Aboveground and

1 Belowground Biomass, Dead Wood and Litter were based on data collected from the extensive array of permanent,
2 annual forest inventory plots and associated models (e.g., live tree belowground biomass estimates) in the U.S.
3 (USDA Forest Service 2015b, 2015c). Carbon conversion factors were applied at the disaggregated level of each
4 inventory plot and then appropriately expanded to population estimates. To ensure consistency in the *Land*
5 *Converted to Forest Land* category where C stock transfers occur between land-use categories, all soil estimates are
6 based on methods from Ogle et al. (2003, 2006) and IPCC (2006).

7 *Carbon in Biomass*

8 Live tree C pools include aboveground and belowground (coarse root) biomass of live trees with diameter at breast
9 height (dbh) of at least 2.54 cm at 1.37 m above the forest floor. Separate estimates were made for above and
10 belowground biomass components. If inventory plots included data on individual trees, above- and belowground
11 tree C was based on Woodall et al. (2011a), which is also known as the component ratio method (CRM), and is a
12 function of volume, species, and diameter. An additional component of foliage, which was not explicitly included in
13 Woodall et al. (2011a), was added to each tree following the same CRM method.

14 Understory vegetation is a minor component of biomass and is defined as all biomass of undergrowth plants in a
15 forest, including woody shrubs and trees less than 2.54 cm dbh. For this Inventory, it was assumed that 10 percent of
16 total understory C mass is belowground (Smith et al. 2006). Estimates of C density were based on information in
17 Birdsey (1996) and biomass estimates from Jenkins et al. (2003). Understory biomass represented over one percent
18 of C in biomass, but its contribution rarely exceeded 2 percent of the total.

19 *Carbon in Dead Organic Matter*

20 Dead organic matter was initially calculated as three separate pools—standing dead trees, downed dead wood, and
21 litter—with C stocks estimated from sample data or from models. The standing dead tree C pool includes
22 aboveground and belowground (coarse root) biomass for trees of at least 12.7 cm dbh. Calculations followed the
23 basic method applied to live trees (Woodall et al. 2011a) with additional modifications to account for decay and
24 structural loss (Domke et al. 2011; Harmon et al. 2011). Downed dead wood estimates are based on measurement of
25 a subset of FIA plots for downed dead wood (Domke et al. 2013; Woodall and Monleon 2008; Woodall et al. 2013).
26 Downed dead wood is defined as pieces of dead wood greater than 7.5 cm diameter, at transect intersection, that are
27 not attached to live or standing dead trees. This includes stumps and roots of harvested trees. To facilitate the
28 downscaling of downed dead wood C estimates from the state-wide population estimates to individual plots, downed
29 dead wood models specific to regions and forest types within each region are used. Litter C is the pool of organic C
30 (also known as duff, humus, and fine woody debris) above the mineral soil and includes woody fragments with
31 diameters of up to 7.5 cm. A subset of FIA plots are measured for litter C. A modeling approach, using litter C
32 measurements from FIA plots (Domke et al. 2016) was used to estimate litter C for every FIA plot used in the
33 estimation framework.

34 *Mineral Soil Carbon Stock Changes*

35 A Tier 2 method is applied to estimate mineral soil C stock changes for *Land Converted to Forest Land* (Ogle et al.
36 2003, 2006; IPCC 2006). For this method, land is stratified by climate, soil types, land use, and land management
37 activity, and then assigned reference carbon levels and factors for the forest land and the previous land use. The
38 difference between the stocks is reported as the stock change under the assumption that the change occurs over 20
39 years. Reference C stocks have been estimated from data in the National Soil Survey Characterization Database
40 (USDA-NRCS 1997), and U.S.-specific stock change factors have been derived from published literature (Ogle et
41 al. 2003, 2006). Land use and land use change patterns are determined from a combination of the Forest Inventory
42 and Analysis Dataset (FIA), the 2010 National Resources Inventory (NRI) (USDA-NRCS 2013), and National Land
43 Cover Dataset (NLCD) (Homer et al. 2007). See Annex 3.12 for more information about this method (Methodology
44 for Estimating N₂O Emissions, CH₄ Emissions and Soil Organic C Stock Changes from Agricultural Soil
45 Management).

46 **Uncertainty and Time-Series Consistency**

47 A quantitative uncertainty analysis placed bounds on the flux estimates for *Land Converted to Forest Land* through
48 a combination of sample-based and model-based approaches to uncertainty for forest ecosystem CO₂ Eq. flux (IPCC

Approach 1). Uncertainty estimates for forest pool C stock changes were developed using the same methodologies as described in the *Forest Land Remaining Forest Land* section for aboveground and biomass ground biomass, dead wood, and litter. The exception was when IPCC default estimates were used for reference C stocks in certain conversion categories (i.e., *Cropland Converted to Forest Land* and *Grassland Converted to Forest Land*). In those cases, the uncertainties associated with the IPCC (2006) defaults were included in the uncertainty calculations. IPCC Approach 2 was used for mineral soils and is described in the *Cropland Remaining Cropland* section.

Uncertainty estimates are presented in Table 6-27 for each land conversion category and C pool. Uncertainty estimates were obtained using a combination of sample-based and model-based approaches for all non-soil C pools (IPCC Approach 1) and a Monte Carlo approach (IPCC Approach 2) was used for mineral soil. Uncertainty estimates were combined using the error propagation model (IPCC Approach 1). The combined uncertainty for all C stocks in *Land Converted to Forest Land* ranged from 10 percent below to 11 percent above the 2015 stock change estimate of -75.2 MMT CO₂ Eq.

Table 6-27: Quantitative Uncertainty Estimates for Forest C Pool Stock Changes (MMT CO₂ Eq. per Year) in 2015 from *Land Converted to Forest Land* by Land Use Change

Source	2015 Flux Estimate	Uncertainty Range Relative to Flux Range ^a

Note: Parentheses indicate net sequestration.

1 In the case of mineral soil estimates which were reported in the 1990 to 2014 Inventory, methodological
2 recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2015.
3 Details on the emission trends through time are described in more detail in the Methodology section above.

4 QA/QC and Verification

5 See QA/QC and Verification section under *Forest land Remaining Forest Land* and *Cropland Remaining Cropland*.

6 Recalculations Discussion

7 This is the second U.S. Inventory report to include a *Land Converted to Forest Land* section containing specific soil
8 C stock change estimates and the first Inventory report to include all C pools for *Land Converted to Forest Land*. In
9 prior Inventory reports (e.g., EPA 2015), the C stock changes from *Land Converted to Forest Land* were a part of
10 the *Forest Land Remaining Forest Land* estimates. See the Recalculations section in *Forest Land Remaining Forest*
11 *Land* for a detailed explanation on overall changes resulting from implementing a different methodological approach
12 in the current Inventory report. These changes, particularly the inclusion of biomass, dead wood and litter in the
13 estimates, resulted in an average annual increase in sequestration of 89.9 MMT CO₂ Eq. relative to the previous
14 Inventory.

15 Planned Improvements

16 A different estimation approach (Woodall et al. 2015a) was used for the forest land category beginning with the
17 1990 to 2014 Inventory with the specific intent of separating *Forest Land Remaining Forest Land* and *Land*
18 *Converted to Forest Land*. While this new approach led to improvements (e.g., disaggregation of forest land area
19 between the land-use categories), there are many improvements still necessary to fully incorporate all C pool
20 estimates and all land-use categories over the entire time series. First, research, in coordination with the other land-
21 use categories, into the length of time that forest land remains in the *Land Converted to Forest Land* category will be
22 undertaken and a mechanism to account for emissions and removals for all IPCC pools in this conversion category
23 will be developed. Second, soil C has historically been reported to a depth of 100 cm in the *Forest Land Remaining*
24 *Forest Land* category (Domke et al. In press) while other land-use categories (e.g., Grasslands and Croplands) report
25 soil carbon to a depth of 20 or 30 cm. To ensure greater consistency in the *Land Converted to Forest Land* category
26 where C stock transfers occur between land-use categories, all mineral soil estimates in the *Land Converted to*
27 *Forest Land* category in this Inventory are based on methods from Ogle et al. (2003, 2006) and IPCC (2006).
28 Methods have recently been developed (Domke et al. In press) to estimate soil C to depths of 20, 30, and 100 cm in
29 the Forest Land category using in situ measurements from the Forest Inventory and Analysis program within the
30 USDA Forest Service and the International Soil Carbon Network. In subsequent Inventories, a common reporting
31 depth will be defined for all land conversion categories and Domke et al. (In press) will be used in the *Forest Land*
32 *Remaining Forest Land* and *Land Converted to Forest Land* categories to ensure consistent reporting across all
33 forest land. Third, due to 5 to 10 year remeasurement periods within the FIA program and limited land use change
34 information available over the entire time-series, estimates presented in this section may not reflect the entire 20-
35 year conversion. Work is underway to integrate the dense time-series of remotely sensed data into a new estimation
36 system which will facilitate land conversion estimation over the entire time series.

6.4 Cropland Remaining Cropland (IPCC Source Category 4B1)

Mineral and Organic Soil Carbon Stock Changes

Carbon (C) in cropland ecosystems occurs in biomass, dead organic matter, and soils. However, C storage in cropland biomass and dead organic matter is relatively ephemeral, with the exception of C stored in perennial woody crop biomass, such as citrus groves and apple orchards. Within soils, C is found in organic and inorganic forms of C, but soil organic C (SOC) is the main source and sink for atmospheric CO₂ in most soils. IPCC (2006) recommends reporting changes in SOC stocks due to agricultural land-use and management activities on both mineral and organic soils.³²

Well-drained mineral soils typically contain from 1 to 6 percent organic C by weight, whereas mineral soils with high water tables for substantial periods during the year may contain significantly more C (NRCS 1999). Conversion of mineral soils from their native state to agricultural land uses can cause up to half of the SOC to be lost to the atmosphere due to enhanced microbial decomposition. The rate and ultimate magnitude of C loss depends on subsequent management practices, climate and soil type (Ogle et al. 2005). Agricultural practices, such as clearing, drainage, tillage, planting, grazing, crop residue management, fertilization, and flooding, can modify both organic matter inputs and decomposition, and thereby result in a net C stock change (Parton et al. 1987; Paustian et al. 1997a; Conant et al. 2001; Ogle et al. 2005). Eventually, the soil can reach a new equilibrium that reflects a balance between C inputs (e.g., decayed plant matter, roots, and organic amendments such as manure and crop residues) and C loss through microbial decomposition of organic matter (Paustian et al. 1997b).

Organic soils, also referred to as *Histosols*, include all soils with more than 12 to 20 percent organic C by weight, depending on clay content (NRCS 1999; Brady and Weil 1999). The organic layer of these soils can be very deep (i.e., several meters), and form under inundated conditions that results in minimal decomposition of plant residues. When organic soils are prepared for crop production, they are drained and tilled, leading to aeration of the soil that accelerates both the decomposition rate and CO₂ emissions.³³ Due to the depth and richness of the organic layers, C loss from drained organic soils can continue over long periods of time, which varies depending on climate and composition (i.e., decomposability) of the organic matter (Armentano and Menges 1986). Due to deeper drainage and more intensive management practices, the use of organic soils for annual crop production (and also settlements) leads to higher C loss rates than drainage of organic soils in grassland or forests (IPCC 2006).

Cropland Remaining Cropland includes all cropland in an Inventory year that has been cropland for a continuous time period of at least 20 years according to the 2012 United States Department of Agriculture (USDA) National Resources Inventory (NRI) land-use survey for non-federal lands (USDA-NRCS 2015) or according to the National Land Cover Dataset for federal lands (Homer et al. 2007; Fry et al. 2011; Homer et al. 2015). Cropland includes all land used to produce food and fiber, in addition to forage that is harvested and used as feed (e.g., hay and silage), and cropland that has been enrolled in the Conservation Reserve Program (CRP) (i.e., considered reserve cropland). Cropland in Alaska is not included in the Inventory, but is a relatively small amount of U.S. cropland area (approximately 28,700 hectares). Some miscellaneous croplands are also not included in the Inventory due to limited understanding of greenhouse gas emissions from these management systems (e.g., aquaculture). This leads to a small discrepancy between the total amount of managed area in *Cropland Remaining Cropland* (see Section 6.1 Representation of the U.S. Land Base) and the cropland area included in the Inventory analysis (1.2 to 1.6 million hectares or 0.8 percent of the total cropland areas in the United States between 1990 and 2015). Improvements are underway to include croplands in Alaska as part of future C inventories.

³² Carbon dioxide emissions associated with liming and urea application are also estimated but are included in the Agriculture chapter of the report.

³³ N₂O emissions from soils are included in the Agricultural Soil Management section.

Carbon dioxide emissions and removals³⁴ due to changes in mineral soil C stocks are estimated using a Tier 3 method for the majority of annual crops (Ogle et al. 2010). A Tier 2 IPCC method is used for the remaining crops not included in the Tier 3 method (see Methodology section for a list of crops in the Tier 2 and 3 methods) (Ogle et al. 2003, 2006). In addition, a Tier 2 method is used for very gravelly, cobbly, or shaley soils (i.e., classified as soils that have greater than 35 percent of soil volume comprised of gravel, cobbles, or shale) regardless of crop, and for additional changes in mineral soil C stocks that are not addressed with the Tier 3 approach (i.e., change in C stocks after 2010 due to CRP enrollment). Emissions from organic soils are estimated using a Tier 2 IPCC method.

Land-use and land management of mineral soils are the largest contributor to total net C stock change, especially in the early part of the time series (see Table 6-28 and Table 6-29). (Note: Estimates after 2012 are based on NRI data from 2012 and therefore do not fully reflect changes occurring in the latter part of the time series). In 2015, mineral soils are estimated to sequester 42.1 MMT CO₂ Eq. from the atmosphere (11.5 MMT C).³⁵ This rate of C storage in mineral soils represents about a 41 percent decrease in the rate since the initial reporting year of 1990. Carbon dioxide emissions from organic soils are 28.0 MMT CO₂ Eq. (7.6 MMT C) in 2015, which is a 7 percent decrease compared to 1990. In total, United States agricultural soils in *Cropland Remaining Cropland* sequestered approximately 14.0 MMT CO₂ Eq. (3.8 MMT C) in 2015.

Table 6-28: Net CO₂ Flux from Soil C Stock Changes in *Cropland Remaining Cropland* (MMT CO₂ Eq.)

Soil Type	1990	2005	2011	2012	2013 ^a	2014 ^a	2015 ^a
Mineral Soils	(71.2)	(56.2)	(47.1)	(49.5)	(43.7)	(42.9)	(42.1)
Organic Soils	30.3	29.7	27.9	28.1	28.1	28.1	28.0
Total Net Flux	(40.9)	(26.5)	(19.1)	(21.4)	(15.6)	(14.8)	(14.0)

^a Quality control uncovered errors in the estimates of mineral soils and the total net flux for 2013, 2014 and 2015, which will be updated following public review. The corrected mineral soil estimates are (47.6), (46.8), and (46.0) MMT CO₂ Eq., respectively for 2013, 2014, 2015, and the total net flux is (19.6), (18.7) and (18.0) MMT CO₂ Eq., respectively for the three years.

Notes: Estimates after 2012 are based on NRI data from 2012 and therefore may not fully reflect changes occurring in the latter part of the time series. Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

Table 6-29: Net CO₂ Flux from Soil C Stock Changes in *Cropland Remaining Cropland* (MMT C)

Soil Type	1990	2005	2011	2012	2013 ^a	2014 ^a	2015 ^a
Mineral Soils	(19.4)	(15.3)	(12.8)	(13.5)	(11.9)	(11.7)	(11.5)
Organic Soils	8.3	8.1	7.6	7.7	7.7	7.7	7.6
Total Net Flux	(11.2)	(7.2)	(5.2)	(5.8)	(4.3)	(4.0)	(3.8)

^a Quality control uncovered errors in the estimates of mineral soils and the total net flux for 2013, 2014 and 2015, which will be updated following public review. The corrected mineral soil estimates are (13.0), (12.8) and (12.6) MMT C, respectively for 2013, 2014 and 2015, and the total net flux is (5.3), (5.1) and (4.9) MMT C, respectively for the three years.

Notes: Estimates after 2012 are based on NRI data from 2012 and therefore may not fully reflect changes occurring in the latter part of the time series. Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

Soil C stocks increase on *Cropland Remaining Cropland* across the entire time series, largely driven by the nearly 10 million hectares of land currently enrolled in CRP (i.e., set-aside program), as well as from increased hay production, adoption of conservation tillage (i.e., reduced- and no-till practices), and intensification of crop

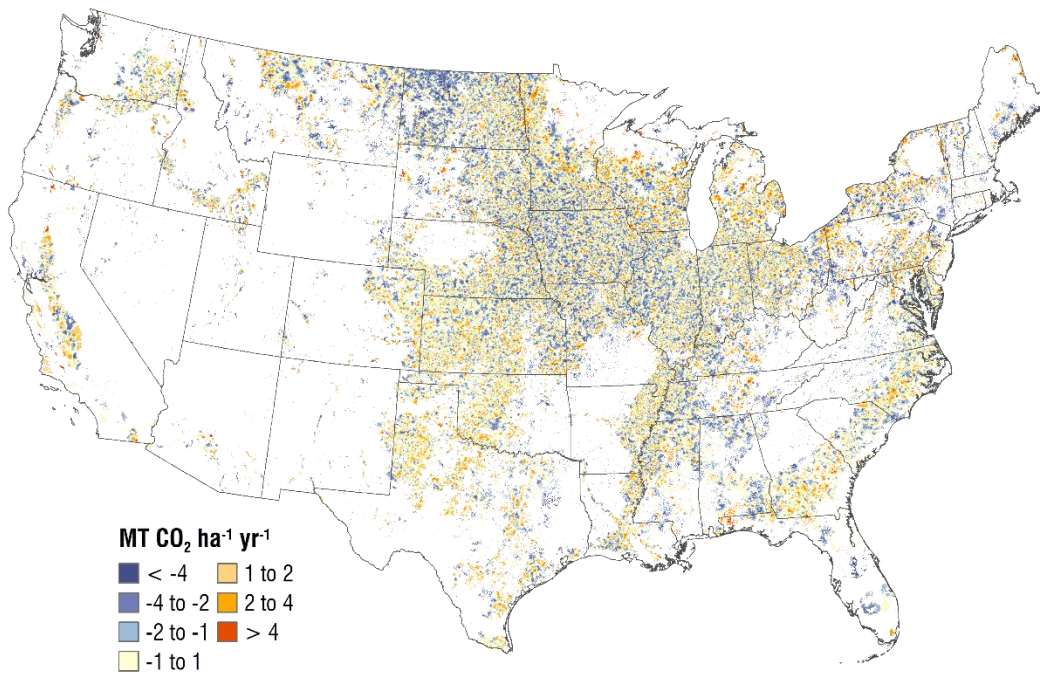

³⁴ Removals occur through uptake of CO₂ into crop and forage biomass that is later incorporated into soil C pools.

³⁵ Quality control uncovered errors in the mineral soil and total net flux estimates for 2015, which will be updated following public review. Based on the revision, soil C stocks increased by 46.0 MMT CO₂ Eq. (12.6 MMT C) in 2015. The total net flux implies C sequestration of 18.0 MMT CO₂ Eq. (4.9 MMT C). The corrected overall trend is a decrease in soil C stock change by 56 percent since the initial reporting year in 1990.

1 production by limiting the use of bare-summer fallow in semi-arid regions. However, there is a decline in the net
2 amount of carbon sequestration (i.e., 2015 is 41 percent less than 1990), and this decline is due to less annual
3 cropland enrolled in the CRP³⁶ that was initiated in 1985. For example, over 1.8 million hectares, which had been
4 enrolled in the CRP, were returned to agricultural production during the last 3 years resulting in a loss of soil C. Soil
5 C losses from drainage of organic soils are relatively stable across the time series with a small decline associated
6 with the land base declining by 7 percent for *Cropland Remaining Cropland* on organic soils since 1990.

7 The spatial variability in the 2015 annual C stock changes are displayed in Figure 6-4 and Figure 6-5 for mineral and
8 organic soils, respectively. Isolated areas with high rates of C accumulation occur throughout the agricultural land
9 base in the United States, but there are more concentrated areas with gains in the northern Great Plains, which has
10 high rates of CRP enrollment. High rates of net C accumulation in mineral soils also occurred in the Corn Belt
11 region, which is the region with the largest amounts of conservation tillage, along with moderate rates of CRP
12 enrollment. The regions with the highest rates of emissions from drainage of organic soils occur in the Southeastern
13 Coastal Region (particularly Florida), upper Midwest and Northeast surrounding the Great Lakes, and isolated areas
14 along the Pacific Coast (particularly California), which coincides with the largest concentrations of organic soils in
15 the United States that are used for agricultural production.

16 **Figure 6-4: Total Net Annual CO₂ Flux for Mineral Soils under Agricultural Management**
17 **within States, 2015, *Cropland Remaining Cropland***

³⁶ The Conservation Reserve Program (CRP) is a land conservation program administered by the Farm Service Agency (FSA). In exchange for a yearly rental payment, farmers enrolled in the program agree to remove environmentally sensitive land from agricultural production and plant species that will improve environmental health and quality. Contracts for land enrolled in CRP are 10 to 15 years in length. The long-term goal of the program is to re-establish valuable land cover to help improve water quality, prevent soil erosion, and reduce loss of wildlife habitat.

1 **Figure 6-5: Total Net Annual CO₂ Flux for Organic Soils under Agricultural Management**
2 **within States, 2015, Cropland Remaining Cropland**

3
4

5 **Methodology**

6 The following section includes a description of the methodology used to estimate changes in soil C stocks for
7 *Cropland Remaining Cropland*, including (1) agricultural land-use and management activities on mineral soils; and
8 (2) agricultural land-use and management activities on organic soils.

9 Soil C stock changes on non-federal lands are estimated for *Cropland Remaining Cropland* (as well as agricultural
10 land falling into the IPCC categories *Land Converted to Cropland*, *Grassland Remaining Grassland*, and *Land*
11 *Converted to Grassland*) according to land-use histories recorded in the USDA NRI survey (USDA-NRCS 2015).
12 The NRI is a statistically-based sample of all non-federal land, and includes approximately 609,211 survey locations
13 in agricultural land for the conterminous United States and Hawaii. Each survey location is associated with an
14 “expansion factor” that allows scaling of C stock changes from NRI survey locations to the entire country (i.e., each
15 expansion factor represents the amount of area with the same land-use/management history as the sample point).
16 Land-use and some management information (e.g., crop type, soil attributes, and irrigation) were collected for each
17 NRI point on a 5-year cycle beginning from 1982 through 1997. For cropland, data had been collected for 4 out of 5
18 years during each survey cycle (i.e., 1979 through 1982, 1984 through 1987, 1989 through 1992, and 1994 through
19 1997). In 1998, the NRI program began collecting annual data, and the annual data are currently available through
20 2012 (USDA-NRCS 2015). NRI survey locations are classified as *Cropland Remaining Cropland* in a given year
21 between 1990 and 2012 if the land use had been cropland for a continuous time period of at least 20 years. NRI
22 survey locations are classified according to land-use histories starting in 1979, and consequently the classifications
23 are based on less than 20 years from 1990 to 1998. This may have led to an overestimation of *Cropland Remaining*
24 *Cropland* in the early part of the time series to the extent that some areas are converted to cropland between 1971
25 and 1978.

26 *Mineral Soil Carbon Stock Changes*

27 An IPCC Tier 3 model-based approach (Ogle et al. 2010) is applied to estimate C stock changes for mineral soils on
28 the majority of land that is used to produce annual crops in the United States. These crops include alfalfa hay,

1 barley, corn, cotton, dry beans, grass hay, grass-clover hay, lentils, oats, onions, peanuts, peas, potatoes, rice,
2 sorghum, soybeans, sugar beets, sunflowers, tobacco, tomatoes, and wheat, but is not applied to estimate C stock
3 changes from other crops or rotations with other crops. The model-based approach uses the DAYCENT
4 biogeochemical model (Parton et al. 1998; Del Grosso et al. 2001, 2011) to estimate soil C stock changes and soil
5 nitrous oxide (N₂O) emissions from agricultural soil management. Carbon and N dynamics are linked in plant-soil
6 systems through the biogeochemical processes of microbial decomposition and plant production (McGill and Cole
7 1981). Coupling the two source categories (i.e., agricultural soil C and N₂O) in a single inventory analysis ensures
8 that there is a consistent treatment of the processes and interactions between C and N cycling in soils.

9 The remaining crops on mineral soils are estimated using an IPCC Tier 2 method (Ogle et al. 2003), including some
10 vegetables, tobacco, perennial/horticultural crops, and crops that are rotated with these crops. The Tier 2 method is
11 also used for very gravelly, cobbly, or shaley soils (greater than 35 percent by volume), and soil C stock changes on
12 federal croplands. Mineral SOC stocks are estimated using a Tier 2 method for these areas because the DAYCENT
13 model, which is used for the Tier 3 method, has not been fully tested for estimating C stock changes associated with
14 these crops and rotations, as well as cobbly, gravelly, or shaley soils. In addition, there is insufficient information to
15 simulate croplands on federal lands using DAYCENT. The Tier 2 method is also used to estimate additional soil C
16 stock changes on lands enrolled in CRP after 2012, which is the last year of data in the NRI time series, using
17 aggregated data on CRP enrollment compiled by the USDA Farm Services Agency.

18 Further elaboration on the methodology and data used to estimate stock changes from mineral soils are described
19 below and in Annex 3.12.

20 *Tier 3 Approach*

21 Mineral SOC stocks and stock changes are estimated using the DAYCENT biogeochemical³⁷ model (Parton et al.
22 1998; Del Grosso et al. 2001, 2011), which is able to simulate cycling of C, N and other nutrients in cropland,
23 grassland, forest, and savanna ecosystems. The DAYCENT model utilizes the soil C modeling framework
24 developed in the Century model (Parton et al. 1987, 1988, 1994; Metherell et al. 1993), but has been refined to
25 simulate dynamics at a daily time-step. The modeling approach uses daily weather data as an input, along with
26 information about soil physical properties. Input data on land use and management are specified at a daily resolution
27 and include land-use type, crop/forage type, and management activities (e.g., planting, harvesting, fertilization,
28 manure amendments, tillage, irrigation, and grazing). The model simulates net primary productivity (NPP) using the
29 NASA-CASA production algorithm MODIS Enhanced Vegetation Index (EVI) products, MOD13Q1 and
30 MYD13Q1, for most croplands³⁸ (Potter et al. 1993, 2007). The model also simulates soil temperature, and water
31 dynamics, in addition to turnover, stabilization, and mineralization of soil organic matter C and nutrients (N, P, K,
32 S). This method is more accurate than the Tier 1 and 2 approaches provided by the IPCC (2006) because the
33 simulation model treats changes as continuous over time as opposed to the simplified discrete changes represented
34 in the default method (see Box 6-5 for additional information).

35 **Box 6-5: Tier 3 Approach for Soil C Stocks Compared to Tier 1 or 2 Approaches**

36 A Tier 3 model-based approach is used to estimate soil C stock changes on the majority of agricultural land on
37 mineral soils. This approach results in a more complete and accurate accounting of soil C stock changes and entails
38 several fundamental differences from the IPCC Tier 1 or 2 methods, as described below.

- 39 (1) The IPCC Tier 1 and 2 methods are simplified and classify land areas into discrete categories based on
40 highly aggregated information about climate (six regions), soil (seven types), and management (eleven
41 management systems) in the United States. In contrast, the Tier 3 model incorporates the same variables
42 (i.e., climate, soils, and management systems) with considerably more detail both temporally and spatially,
43 and captures multi-dimensional interactions through the more complex model structure.

³⁷ Biogeochemical cycles are the flow of chemical elements and compounds between living organisms and the physical environment.

³⁸ NPP is estimated with the NASA-CASA algorithm for most of the cropland that is used to produce major commodity crops in the central United States from 2000 to 2012. Other regions and years prior to 2000 are simulated with a method that incorporates water, temperature and moisture stress on crop production (see Metherell et al. 1993), but does not incorporate the additional information about crop condition provided with remote sensing data.

- 1 (2) The IPCC Tier 1 and 2 methods have a simplified spatial resolution in which data are aggregated to soil
2 types in climate regions, of which there about 30 of combinations in the United States. In contrast, the Tier
3 3 model simulates soil C dynamics at more than 300,000 individual NRI survey locations in individual
4 fields.
- 5 (3) The IPCC Tier 1 and 2 methods use simplified equilibrium step changes for changes in C emissions. In
6 contrast, the Tier 3 approach simulates a continuous time period. More specifically, the DAYCENT model
7 (i.e., daily time-step version of the Century model) simulates soil C dynamics (and CO₂ emissions and
8 uptake) on a daily time step based on C emissions and removals from plant production and decomposition
9 processes. These changes in soil C stocks are influenced by multiple sources that affect primary production
10 and decomposition, including changes in land use and management, weather variability and secondary
11 feedbacks between management activities, climate, and soils.
-

12

13 Historical land-use patterns and irrigation histories are simulated with DAYCENT based on the 2012 USDA NRI
14 survey (USDA-NRCS 2015). Additional sources of activity data are used to supplement the land-use information
15 from the NRI. The Conservation Technology Information Center (CTIC 2004) provided annual data on tillage
16 activity at the county level for the conterminous United States between 1989 and 2004, and these data are adjusted
17 for long-term adoption of no-till agriculture (Towery 2001). No-till adoption is assumed to remain constant from
18 2005 through 2015 due to lack of data, but there is a planned improvement to update the tillage histories with a
19 dataset that was recently released by the USDA (Conservation Effects Assessment Program Data, See Planned
20 Improvements section). Information on fertilizer use and rates by crop type for different regions of the United States
21 are obtained primarily from the USDA Economic Research Service. The data collection program was known as the
22 Cropping Practices Surveys through 1995 (USDA-ERS 1997), and then became the Agricultural Resource
23 Management Surveys (ARMS) (USDA-ERS 2015). Additional data are compiled through other sources particularly
24 the National Agricultural Statistics Service (NASS 1992, 1999, 2004). Frequency and rates of manure application to
25 cropland for 1997 are estimated from data compiled by the USDA Natural Resources Conservation Service
26 (Edmonds et al. 2003), and then adjusted using county-level estimates of manure available for application in other
27 years. Specifically, county-scale ratios of manure available for application to soils in other years relative to 1997 are
28 used to adjust the area amended with manure (see Annex 3.12 for further details). Greater availability of managed
29 manure N relative to 1997 is assumed to increase the area amended with manure, while reduced availability of
30 manure N relative to 1997 is assumed to reduce the amended area. Data on the county-level N available for
31 application are estimated for managed systems based on the total amount of N excreted in manure minus N losses
32 during storage and transport, and include the addition of N from bedding materials. Nitrogen losses include direct
33 N₂O emissions, volatilization of ammonia and NO_x, N runoff and leaching, and the N in poultry manure used as a
34 feed supplement. More information on livestock manure production is available in Section 5.2 - Manure
35 Management and Annex 3.11.

36 Daily weather data are another input to the model simulations. These data are based on a 4 kilometer gridded
37 product from the PRISM Climate Group (2015). Soil attributes are obtained from the Soil Survey Geographic
38 Database (SSURGO) (Soil Survey Staff 2016). The C dynamics at each NRI point are simulated 100 times as part of
39 the uncertainty analysis, yielding a total of over 18 million simulation runs for the analysis. Uncertainty in the C
40 stock estimates from DAYCENT associated with parameterization and model algorithms are adjusted using a
41 structural uncertainty estimator accounting for uncertainty in model algorithms and parameter values (Ogle et al.
42 2007, 2010). Carbon stocks and 95 percent confidence intervals are estimated for each year between 1990 and 2012
43 using the NRI survey data, which is available through 2012. C stock change rates from 2013 to 2015 are assumed to
44 be similar to 2012 for this Inventory.³⁹ However, the areas may have changed through the process in which the NRI
45 survey data are reconciled with the Forest Inventory and Analysis (FIA) survey data and the National Land Cover
46 Dataset (Homer et al. 2007; Fry et al. 2011; Homer et al. 2015). This process ensures that the areas of *Forest Land*
47 *Remaining Forest Land* and *Land Converted to Forest Land* are consistent in all three datasets, and leads to some
48 modification of other lands use areas to ensure the total land area of the United States does not change. For example,
49 if the FIA estimate less *Cropland Converted to Forest Land* than the NRI, then the amount of area for this land use
50 conversion is reduced in the NRI dataset and re-classified as *Cropland Remaining Cropland* (See Section 0,

³⁹ Note: CRP enrollment is modified from 2013 to 2015 as described in the section on the Tier 2 Approach.

1 Representation of the U.S. Land Base for more information). Future Inventories will be updated with new NRI
2 activity data when the data are made available, and the time series from 2013 to 2015 will be recalculated.

3 *Tier 2 Approach*

4 In the IPCC Tier 2 method, data on climate, soil types, land-use, and land management activity are used to classify
5 land area and apply appropriate soil C stock change factors (Ogle et al. 2003, 2006). Reference C stocks are
6 estimated using the National Soil Survey Characterization Database (NRCS 1997) with cultivated cropland as the
7 reference condition, rather than native vegetation as used in IPCC (2006). Soil measurements under agricultural
8 management are much more common and easily identified in the National Soil Survey Characterization Database
9 (NRCS 1997) than are soils under a native condition, and therefore cultivated cropland provided a more robust
10 sample for estimating the reference condition. U.S.-specific C stock change factors are derived from published
11 literature to determine the impact of management practices on SOC storage (Ogle et al. 2003, Ogle et al. 2006). The
12 factors include changes in tillage, cropping rotations, intensification, and land-use change between cultivated and
13 uncultivated conditions. U.S. factors associated with organic matter amendments are not estimated due to an
14 insufficient number of studies in the United States to analyze the impacts. Instead, factors from IPCC (2006) are
15 used to estimate the effect of those activities.

16 Climate zones in the United States are classified using mean precipitation and temperature (1950 to 2000) variables
17 from the WorldClim data set (Hijmans et al. 2005) and potential evapotranspiration data from the Consortium for
18 Spatial Information (CGIAR-CSI) (Zomer et al. 2008, 2007) (Figure A-15). IPCC climate zones are then assigned to
19 NRI point locations.

20 Activity data are primarily based on the historical land-use/management patterns recorded in the 2012 NRI (USDA-
21 NRCS 2015). Each NRI point is classified by land use, soil type, climate region, and management condition. Survey
22 locations on federal lands are included in the NRI, but land use and cropping history are not compiled at these
23 locations in the survey program (i.e., NRI is restricted to data collection on non-federal lands). Land-use patterns at
24 the NRI survey locations on federal lands are based on the National Land Cover Database (NLCD) (Fry et al. 2011;
25 Homer et al. 2007; Homer et al. 2015). Classification of cropland area by tillage practice is based on data from the
26 Conservation Technology Information Center (CTIC 2004; Towery 2001) as described in the Tier 3 approach above.
27 Activity data on wetland restoration of Conservation Reserve Program land are obtained from Euliss and Gleason
28 (2002). Manure N amendments over the inventory time period are based on application rates and areas amended
29 with manure N from Edmonds et al. (2003), in addition to the managed manure production data discussed in the
30 methodology subsection for the Tier 3 approach.

31 Utilizing information from these data sources, SOC stocks for mineral soils are estimated 50,000 times for each year
32 in the time series, using a Monte Carlo stochastic simulation approach and probability distribution functions for
33 U.S.-specific stock change factors, reference C stocks, and land-use activity data (Ogle et al. 2002; Ogle et al. 2003;
34 Ogle et al. 2006). The annual C stock change rates from 2013 through 2015 for the Tier 2 method are assumed to be
35 similar to 2012, but the areas may be adjusted through the process of reconciling NRI and NLCD with the FIA data
36 (See section on the Tier 3 Approach for more information). As with the Tier 3 method, future Inventories will be
37 updated with new NRI activity data when the data are made available, and the time series will be recalculated (see
38 Planned Improvements section).

39 *Additional Mineral Soil C Stock Change*

40 Annual C stock change estimates for mineral soils between 2013 and 2015 are adjusted to account for additional C
41 stock changes associated with gains or losses in soil C after 2012 due to changes in CRP enrollment (USDA-FSA
42 2015). The change in enrollment relative to 2012 is based on data from USDA-FSA (2015) for 2012 through 2015.
43 The differences in mineral soil areas are multiplied by 0.5 metric tons C per hectare per year to estimate the net
44 effect on soil C stocks. The stock change rate is based on country-specific factors and the IPCC default method (see
45 Annex 3.12 for further discussion).

46 *Organic Soil Carbon Stock Changes*

47 Annual C emissions from drained organic soils in *Cropland Remaining Cropland* are estimated using the Tier 2
48 method provided in IPCC (2006), with U.S.-specific C loss rates (Ogle et al. 2003) rather than default IPCC rates.
49 The final estimates included a measure of uncertainty as determined from the Monte Carlo Stochastic Simulation

1 with 50,000 iterations. Emissions are based on the annual data for drained organic soils from 1990 to 2012 for
 2 *Cropland Remaining Cropland* areas in the 2012 NRI (USDA-NRCS 2015). The annual emission rates estimated for
 3 2012 are applied to 2013 through 2015, but the areas may be adjusted through the process of reconciling NRI and
 4 NLCD with the FIA data. (See section on the Tier 3 Approach for more information.) Future Inventories will be
 5 updated with new NRI activity data for 2012 through 2015 when the data are made available, and the time series
 6 will be recalculated (see Planned Improvements section).

7 **Uncertainty and Time-Series Consistency**

8 Uncertainty associated with the *Cropland Remaining Cropland* land-use category is addressed for changes in
 9 agricultural soil C stocks (including both mineral and organic soils). Uncertainty estimates are presented in Table
 10 6-30 for each subsource (mineral soil C stocks and organic soil C stocks) and the methods that are used in the
 11 Inventory analyses (i.e., Tier 2 and Tier 3). Uncertainty for the Tier 2 and 3 approaches is derived using a Monte
 12 Carlo approach (see Annex 3.12 for further discussion), but the C stock changes from the individual Tier 2 and 3
 13 approaches are combined using the simple error propagation method provided by the IPCC (2006). The combined
 14 uncertainty is calculated by taking the square root of the sum of the squares of the standard deviations of the
 15 uncertain quantities. The combined uncertainty for soil C stocks in *Cropland Remaining Cropland* ranged from 230
 16 percent below to 237 percent above the 2015 stock change estimate of -14.0 MMT CO₂ Eq.⁴⁰

17 **Table 6-30: Approach 2 Quantitative Uncertainty Estimates for Soil C Stock Changes**
 18 **occurring within *Cropland Remaining Cropland* (MMT CO₂ Eq. and Percent)**

Source	2015 Flux Estimate ^a (MMT CO ₂ Eq.)	Uncertainty Range Relative to Flux Estimate ^{a,b}			
		(MMT CO ₂ Eq.)		(%)	
		Lower Bound	Upper Bound	Lower Bound	Upper Bound
Mineral Soil C Stocks: Cropland Remaining Cropland, Tier 3 Inventory Methodology	(42.7)	(73.5)	(11.9)	-72%	72%
Mineral Soil C Stocks: Cropland Remaining Cropland, Tier 2 Inventory Methodology	(2.7)	(4.2)	(1.4)	-55%	48%
Mineral Soil C Stocks: Cropland Remaining Cropland (Change in CRP enrollment relative to 2003)	3.3	1.6	4.9	-50%	50%
Organic Soil C Stocks: Cropland Remaining Cropland, Tier 2 Inventory Methodology	28.0	18.4	40.4	-34%	44%
Combined Uncertainty for Flux associated with Agricultural Soil Carbon Stock Change in Cropland Remaining Cropland	(14.0)	(46.4)	19.2	-230%	237%

^a Quality control uncovered errors in the estimate and uncertainty for 2015, which will be updated following public review. The corrected Tier 3 mineral soil C stock change is (46.6) MMT CO₂ Eq., with an uncertainty ranging from -78 percent to +78 percent. The corrected combined flux estimate for 2015 is (18.0) MMT CO₂ Eq., with an uncertainty ranging from -210 percent to 214 percent.

^b Range of C stock change estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval. Notes: Parentheses indicate net sequestration.

19 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 20 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 21 above.

22 Uncertainty is also associated with lack of reporting of agricultural woody biomass and dead organic matter C stock
 23 changes. The IPCC (2006) does not recommend reporting of annual crop biomass in Cropland Remaining Cropland
 24 because all of the biomass senesces each year and so there is no long term storage of C in this pool. For woody

⁴⁰ Quality control uncovered errors in the estimate and uncertainty for 2015, which will be updated following public review. Based on the revision, soil C stocks increased by 18.0 MMT CO₂ Eq. in 2015, with an uncertainty ranging from -210 percent below to 214 percent above the estimate.

1 plants, biomass C stock changes are likely minor in perennial crops, such as orchards and nut plantations. There will
2 be some removal and replanting of tree crops each year, but the net effect on biomass C stock changes is probably
3 minor because the overall area is relatively constant across time series. In contrast, agroforestry practices, such as
4 shelterbelts, riparian forests and intercropping with trees, may be significantly changing biomass C stocks over the
5 Inventory times series, at least in some regions of the United States, but there are currently no datasets to evaluate
6 the trends. Changes in litter C stocks are also assumed to be negligible in croplands over annual time frames,
7 although there are certainly significant changes at sub-annual time scales across seasons. However, this trend may
8 change in the future, particularly if crop residue becomes a viable feedstock for bioenergy production.

9 **QA/QC and Verification**

10 Quality control measures included checking input data, model scripts, and results to ensure data are properly
11 handled throughout the inventory process. Inventory reporting forms and text are reviewed and revised as needed to
12 correct transcription errors. Results from the DAYCENT model are compared to field measurements, and a
13 statistical relationship has been developed to assess uncertainties in the predictive capability of the model. The
14 comparisons include 92 long-term experiments, representing about 908 combinations of management treatments
15 across all of the sites (see Ogle et al. 2007 and Annex 3.12 for more information).

16 **Recalculations Discussion**

17 Methodological recalculations in the current Inventory are associated with the following improvements: (1) driving
18 the DAYCENT simulations with updated input data for land management from the National Resources Inventory
19 from 1979 through 2012; (2) increasing the number of experimental study sites used to quantify model uncertainty;
20 (3) DAYCENT model development to improve the simulation of soil temperature; and (4) improvements in the
21 cropping and land use histories that are simulated in DAYCENT between 1950 and 1979 to reduce the amount of
22 grassland converted into cropland when the NRI histories begin in 1979 (Note the histories generate initial values
23 for the model state variables, including the initial soil organic C stock values; more detail is provide in Annex 3.12).
24 As a result of these improvements, SOC stocks increased by an average of 7.5 MMT CO₂ Eq. across the time series,
25 which is an 18 percent increase in the reported soil C stock changes compared to the previous Inventory.⁴¹ The
26 largest driver of this change is associated with corrective actions taken to more accurately represent the land use
27 histories prior to 1979.

28 **Planned Improvements**

29 There are several planned improvements underway. The DAYCENT model will be refined to simulate soil organic
30 C stock changes to a depth of at least 30 cm. Improvements are also underway to more accurately simulate plant
31 production. Crop parameters associated with temperature effects on plant production will be further improved in
32 DAYCENT with additional model calibration. Senescence events following grain filling in crops, such as wheat, are
33 being modified based on recent model algorithm development, and will be incorporated. Experimental study sites
34 will continue to be added for quantifying model structural uncertainty.

35 There is an effort underway to update the time series of management data with information from the USDA-NRCS
36 Conservation Effects Assessment Program (CEAP). This improvement will fill several gaps in the management data
37 including more specific data on fertilizer rates, updated tillage practices, and more information on planting and
38 harvesting dates for crops.

39 Improvements are underway to simulate crop residue burning in the DAYCENT model based on the amount of crop
40 residues burned according to the data that is used in the Field Burning of Agricultural Residues source category (see
41 Section 5.7). This improvement will more accurately represent the C inputs to the soil that are associated with
42 residue burning.

⁴¹ Quality control uncovered errors in the estimate and uncertainty for 2013, 2014, 2015, which will be updated following public review. These corrections impact the comparison between the prior and current Inventories in the Recalculation Discussion, which will also be updated after public review.

1 The inventory will include an analysis of C stock changes in Alaska for cropland and managed grassland, using the
2 Tier 2 method for mineral and organic soils that is described earlier in this section. This analysis will initially focus
3 on land use change, which typically has a larger impact on soil C stock changes, but will be further refined over time
4 to incorporate more of the management data.

5 All of these improvements are expected to be completed for the 1990 through 2017 Inventory (2019 submission to
6 the UNFCCC). However, the time line may be extended if there are insufficient resources to fund all or part of these
7 planned improvements.

8 6.5 Land Converted to Cropland (IPCC Source 9 Category 4B2)

10 *Land Converted to Cropland* includes all cropland in an Inventory year that had been in another land use(s) during
11 the previous 20 years (USDA-NRCS 2015), and used to produce food or fiber, or forage that is harvested and used
12 as feed (e.g., hay and silage). For example, grassland or forestland converted to cropland during the past 20 years
13 would be reported in this category. Recently converted lands are retained in this category for 20 years as
14 recommended by IPCC (2006). This Inventory includes all croplands in the conterminous United States and Hawaii,
15 but does not include a minor amount of *Land Converted to Cropland* in Alaska. Some miscellaneous croplands are
16 also not included in the Inventory due to limited understanding of greenhouse gas dynamics in management systems
17 (e.g., aquaculture) or climate zones (e.g., boreal climates). Consequently, there is a discrepancy between the total
18 amount of managed area in *Land Converted to Cropland* (see Section 6.1 Representation of the U.S. Land Base) and
19 the cropland area included in the Inventory. Improvements are underway to include croplands in Alaska and
20 miscellaneous crops in future C inventories.

21 Land use change can lead to large losses of C to the atmosphere, particularly conversions from forest land
22 (Houghton et al. 1983). Moreover, conversion of forest to another land use (i.e., deforestation) is one of the largest
23 anthropogenic sources of emissions to the atmosphere globally (Schimel 1995), although this source may be
24 declining according to a recent assessment (Tubiello et al. 2015).

25 The 2006 IPCC Guidelines recommend reporting changes in biomass, dead organic matter and soil organic carbon
26 (SOC)⁴² stocks with land use change. All SOC stock changes are estimated and reported for *Land Converted to*
27 *Cropland*, but for belowground biomass, dead wood and litter pools reporting is limited to *Forest Land Converted to*
28 *Cropland*.⁴³

29 Loss of aboveground woody biomass C from *Forest Land Converted to Cropland* is the largest contributor to C loss
30 throughout the time series, accounting for approximately 66 percent of the total emissions (Table 6-31 and Table
31 6-32). *Grassland Converted to Cropland* is the largest source of emissions associated with soil C pools across the
32 time-series (accounting for approximately 93 percent of the average loss of soil C) because the area of *Grassland*
33 *Converted to Cropland* is significantly higher than for other land use conversions to cropland. The net change in
34 total C stocks for 2015 led to CO₂ emissions to the atmosphere of 28.6 MMT CO₂ Eq. (7.8 MMT C), including 10.3
35 MMT CO₂ Eq. (2.8 MMT C) from aboveground biomass C losses, 2.3 MMT CO₂ Eq. (0.6 MMT C) from
36 belowground biomass C losses, 1.8 MMT CO₂ Eq. (0.5 MMT C) from dead wood C losses, 1.7 MMT CO₂ Eq. (0.5
37 MMT C) from litter C losses, 8.9 MMT CO₂ Eq. (2.4 MMT C) from mineral soils and 3.7 MMT CO₂ Eq. (1.0 MMT

⁴² Carbon dioxide emissions associated with liming and urea application are also estimated but are included in the Agriculture chapter of the report.

⁴³ Changes in biomass C stocks are not currently reported for other land use conversions (other than forest land) to cropland, but this is a planned improvement for a future inventory. Note: changes in dead organic matter are assumed to negligible for other land use conversions (i.e., other than forest land) to cropland based on the Tier 1 method in IPCC (2006).

C) from drainage and cultivation of organic soils.⁴⁴ Emissions in 2015 are 72 percent lower than the emissions in the initial reporting year of 1990, largely due to a reduction in the area of *Forest Land Converted to Cropland*.

Table 6-31: Net CO₂ Flux from Soil C Stock Changes in *Land Converted to Cropland* by Land Use Change Category (MMT CO₂ Eq.)

+ Does not exceed 0.05 MMT C

^a Quality control uncovered errors in the estimates for 2013, 2014 and 2015 for mineral soils in *Grassland Converted to Cropland*, Total Mineral Soil Flux and the Total Net Flux, which will be updated following public review. The corrected mineral soil estimates for *Grassland Converted to Cropland* are 4.1, 4.1, and 4.1 MMT C, respectively for 2013, 2014, 2015; the total mineral net flux is 4.2, 4.2, and 4.2 MMT C, respectively for the three years; and the total net flux for *Land Converted to Cropland* is 9.6, 9.6, and 9.6 MMT C, respectively for the three years.

Notes: Estimates after 2012 are based on NRI data from 2012 and therefore may not fully reflect changes occurring in the latter part of the time series. Totals may not sum due to independent rounding.

1 Methodology

2 The following section includes a description of the methodology used to estimate changes in C stocks for *Land*
3 *Converted to Cropland*, including: (1) loss of aboveground and belowground biomass, dead wood and litter C with
4 conversion of forest lands to cropland; (2) agricultural land-use and management activities on mineral soils; and (3)
5 agricultural land-use and management activities on organic soils.

6 Biomass, Dead Biomass and Litter Carbon Stock Changes

7 A Tier 2 method is applied to estimate aboveground biomass C stock changes for *Forest Land Converted to*
8 *Cropland*. For this method, forest land conversions to croplands were identified in each state and C density estimates
9 were compiled by state for aboveground biomass, belowground biomass, dead wood, and litter for croplands
10 (assumed to be zero since no reference biomass C density estimates exist) and forest land use categories. The
11 difference between the stocks is reported as the stock change under the assumption that the change occurred in the
12 year of the conversion. Reference C density estimates (i.e., aboveground biomass, belowground biomass, dead
13 wood, and litter) for the forest land use have been estimated from data in the Forest Inventory and Analysis (FIA)
14 program within the USDA Forest Service (USDA Forest Service 2015). If FIA plots include data on individual trees,
15 aboveground and belowground C density estimates are based on Woodall et al. (2011). Aboveground and
16 belowground biomass estimates also include live understory which is a minor component of biomass defined as all
17 biomass of undergrowth plants in a forest, including woody shrubs and trees less than 2.54 cm dbh. For this
18 Inventory, it was assumed that 10 percent of total understory C mass is belowground (Smith et al. 2006). Estimates
19 of C density are based on information in Birdsey (1996) and biomass estimates from Jenkins et al. (2003). If FIA
20 plots include data on standing dead trees, standing dead tree C density is estimated following the basic method

1 applied to live trees (Woodall et al. 2011) with additional modifications to account for decay and structural loss
2 (Domke et al. 2011; Harmon et al. 2011). If FIA plots include data on downed dead wood, downed dead wood C
3 density is estimated based on measurements of a subset of FIA plots for downed dead wood (Domke et al. 2013;
4 Woodall and Monleon 2008). Downed dead wood is defined as pieces of dead wood greater than 7.5 cm diameter, at
5 transect intersection, that are not attached to live or standing dead trees. This includes stumps and roots of harvested
6 trees. To facilitate the downscaling of downed dead wood C estimates from the state-wide population estimates to
7 individual plots, downed dead wood models specific to regions and forest types within each region are used. Litter C
8 is the pool of organic C (also known as duff, humus, and fine woody debris) above the mineral soil and includes
9 woody fragments with diameters of up to 7.5 cm. A subset of FIA plots are measured for litter C. If FIA plots
10 include litter material, a modeling approach using litter C measurements from FIA plots is used to estimate litter C
11 density (Domke et al. 2016). See Annex 3.13 for more information about reference C density estimates for forest
12 land.

13 **Soil Carbon Stock Changes**

14 SOC stock changes are estimated for *Land Converted to Cropland* according to land-use histories recorded in the
15 2012 USDA NRI survey for non-federal lands (USDA-NRCS 2015). Land-use and some management information
16 (e.g., crop type, soil attributes, and irrigation) had been collected for each NRI point on a 5-year cycle beginning in
17 1982. In 1998, the NRI program began collecting annual data, which are currently available through 2012 (USDA-
18 NRCS 2015). NRI survey locations are classified as *Land Converted to Cropland* in a given year between 1990 and
19 2012 if the land use is cropland but had been another use during the previous 20 years. NRI survey locations are
20 classified according to land-use histories starting in 1979, and consequently the classifications are based on less than
21 20 years from 1990 to 1998, which may have led to an underestimation of *Land Converted to Cropland* in the early
22 part of the time series to the extent that some areas are converted to cropland from 1971 to 1978. For federal lands,
23 the land use history is derived from land cover changes in the National Land Cover Dataset (Homer et al. 2007; Fry
24 et al. 2011; Homer et al. 2015).

25 *Mineral Soil Carbon Stock Changes*

26 An IPCC Tier 3 model-based approach (Ogle et al. 2010) is applied to estimate C stock changes for mineral soils on
27 the majority of land that is used to produce annual crops in the United States. These crops include alfalfa hay,
28 barley, corn, cotton, dry beans, grass hay, grass-clover hay, lentils, oats, onions, peanuts, peas, potatoes, rice,
29 sorghum, soybeans, sugar beets, sunflowers, tobacco, tomatoes, and wheat. SOC stock changes on the remaining
30 soils are estimated with the IPCC Tier 2 method (Ogle et al. 2003), including land used to produce some vegetables
31 and perennial/horticultural crops and crops rotated with these crops; land on very gravelly, cobbly, or shaley soils
32 (greater than 35 percent by volume); and land converted from another land use or federal ownership.⁴⁵

33 *Tier 3 Approach.* For the Tier 3 method, mineral SOC stocks and stock changes are estimated using the DAYCENT
34 biogeochemical model (Parton et al. 1998; Del Grosso et al. 2001, 2011). The DAYCENT model utilizes the soil C
35 modeling framework developed in the Century model (Parton et al. 1987, 1988, 1994; Metherell et al. 1993), but has
36 been refined to simulate dynamics at a daily time-step. National estimates are obtained by using the model to
37 simulate historical land-use change patterns as recorded in the USDA NRI (USDA-NRCS 2015). Carbon stocks and
38 95 percent confidence intervals are estimated for each year between 1990 and 2012, and C stock changes from 2012
39 to 2015 are assumed to be similar to 2012. Future inventories will be updated with new activity data when the data
40 are made available, and the time series will be recalculated (See Planned Improvements section in *Cropland*
41 *Remaining Cropland*). See the *Cropland Remaining Cropland* section for additional discussion of the Tier 3
42 methodology for mineral soils.

43 *Tier 2 Approach.* For the mineral soils not included in the Tier 3 analysis, SOC stock changes are estimated using a
44 Tier 2 Approach for *Land Converted to Cropland* as described in the Tier 2 Approach for mineral soils in the
45 *Cropland Remaining Cropland* section.

⁴⁵ Federal land is not a land use, but rather an ownership designation that is treated as grassland for purposes of these calculations. The specific land use on federal lands is not identified in the NRI survey (USDA-NRCS 2015).

1 *Organic Soil Carbon Stock Changes*

2 Annual C emissions from drained organic soils in *Land Converted to Cropland* are estimated using the Tier 2
 3 method provided in IPCC (2006), with U.S.-specific C loss rates (Ogle et al. 2003) as described in the *Cropland*
 4 *Remaining Cropland* section for organic soils.

5 **Uncertainty and Time-Series Consistency**

6 The uncertainty analysis for biomass, dead wood and litter C losses with *Forest Land Converted to Cropland* is
 7 conducted in the same way as the uncertainty assessment for forest ecosystem C flux in the *Forest Land Remaining*
 8 *Forest Land* category. Sample and model-based error are combined using simple error propagation methods
 9 provided by the IPCC (2006). For additional details see the Uncertainty Analysis in Annex 3.13. The uncertainty
 10 analyses for mineral soil C stock changes using the Tier 3 and Tier 2 methodologies are based on a Monte Carlo
 11 approach that is described for *Cropland Remaining Cropland*. The uncertainty for annual C emission estimates from
 12 drained organic soils in *Land Converted to Cropland* is estimated using a Monte Carlo approach, which is also
 13 described in the *Cropland Remaining Cropland* section.

14 Uncertainty estimates are presented in Table 6-33 for each subsource (i.e., biomass C stocks, dead wood C stocks,
 15 litter C stocks, mineral soil C stocks and organic soil C stocks) and the method applied in the Inventory analysis
 16 (i.e., Tier 2 and Tier 3). Uncertainty estimates from the Tier 2 and 3 approaches are combined using the simple error
 17 propagation methods provided by the IPCC (2006), i.e., by taking the square root of the sum of the squares of the
 18 standard deviations of the uncertain quantities. The combined uncertainty for total C stocks in *Land Converted to*
 19 *Cropland* ranged from 38 percent below to 42 percent above the 2015 stock change estimate of 28.6 MMT CO₂
 20 Eq.⁴⁶

21 **Table 6-33: Approach 2 Quantitative Uncertainty Estimates for Soil C Stock Changes**
 22 **occurring within *Land Converted to Cropland* (MMT CO₂ Eq. and Percent)**

Source	2015 Flux Estimate ^a (MMT CO ₂ Eq.)	Uncertainty Range Relative to Flux Estimate ^{a,b} (MMT CO ₂ Eq.) (%)

Organic Soil C Stocks: Tier 2	3.7	1.1	9.5	-69%	160%

+ Does not exceed 0.05 MMT CO₂ Eq.

^a Quality control uncovered errors in the 2015 estimates for mineral soils in *Grassland Converted to Cropland* for Tier 3, Total *Grassland Converted to Cropland*, Total Mineral Soil Flux for Tier 3, and the Total Net Flux for *Land Converted Cropland*, which will be updated following public review. The corrected estimate for mineral soils in *Grassland Converted to Cropland* for Tier 3 is 13.4 MMT CO₂ Eq. for 2015 with an uncertainty ranging from -84 percent to 84 percent; *Grassland Converted to Cropland* is 18.1 MMT CO₂ Eq. for 2015 with an uncertainty ranging from -65 percent to 65 percent; the total Tier 3 mineral stock change is also 13.4 MMT CO₂ Eq. with uncertainty ranging from -84 percent to 84 percent; and the total net flux for *Land Converted to Cropland* is 35.3 MMT CO₂ Eq. with uncertainty ranging from -34 percent to 36 percent.

^b Range of C stock change estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Notes: Totals may not sum due to independent rounding. Parentheses indicate negative values or net sequestration.

1 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
2 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
3 above.

4 Uncertainty is also associated with lack of reporting of agricultural biomass and dead organic matter C stock
5 changes. Biomass C stock changes are likely minor in perennial crops, such as orchards and nut plantations, given
6 the small amount of change in land used to produce these commodities in the United States. In contrast, agroforestry
7 practices, such as shelterbelts, riparian forests and intercropping with trees, may have led to significant changes in
8 biomass C stocks, at least in some regions of the United States. However, there are currently no datasets to evaluate
9 the trends. Changes in dead organic matter C stocks are assumed to be negligible with conversion of land to
10 croplands with the exception of forest lands, which are included in this analysis. This assumption will be further
11 explored in a future analysis.

12 QA/QC and Verification

13 See the QA/QC and Verification section in *Cropland Remaining Cropland*.

14 Recalculations Discussion

15 Methodological recalculations in the current Inventory are associated with the following improvements: (1) driving
16 the DAYCENT simulations with updated input data for land use and management from the National Resources
17 Inventory extending the time series through 2012; (2) modifying the number of experimental study sites used to
18 quantify model uncertainty; (3) DAYCENT model development to improve the simulation of soil temperature; (4)
19 improvements in the cropping and land use histories that are simulated in DAYCENT between 1950 and 1979 that
20 generate initial values for the model state variables, including the initial soil organic C stock values; and (5)
21 incorporating belowground biomass, dead wood and litter C stock losses with *Forest Land Converted to Cropland*.
22 As a result of these improvements to the Inventory, *Land Converted to Cropland* have a larger reported loss of C,
23 estimated at 19.1 MMT CO₂ Eq. over the time series.⁴⁷ This represents a 45 percent increase in the losses of carbon
24 with *Land Converted to Cropland* compared to the previous Inventory, and is largely driven by reporting
25 belowground biomass, dead wood and litter C loss from *Forest Land Converted to Croplands*.

⁴⁷ Quality control uncovered errors in the estimate and uncertainty for 2013, 2014, 2015, which will be updated following public review. These corrections impact the comparison between the prior and current Inventories in the Recalculation Discussion, which will also be updated after public review.

1 **Planned Improvements**

2 Soil C stock changes with land use conversion from forest land to cropland are undergoing further evaluation to
3 ensure consistency in the time series. Different methods are used to estimate soil C stock changes in forest land and
4 croplands, and while the areas have been reconciled between these land uses, there has been limited evaluation of
5 the consistency in C stock changes with conversion from forest land to cropland. Additional planned improvements
6 are discussed in the *Cropland Remaining Cropland* section.

7 **6.6 Grassland Remaining Grassland (IPCC** 8 **Source Category 4C1)**

9 **Soil Carbon Stock Changes (IPCC Source Category 3B3a)**

10 *Grassland Remaining Grassland* includes all grassland in an Inventory year that had been grassland for a continuous
11 time period of at least 20 years (USDA-NRCS 2015). Grassland includes pasture and rangeland that are primarily,
12 but not exclusively used for livestock grazing. Rangelands are typically extensive areas of native grassland that are
13 not intensively managed, while pastures are typically seeded grassland (possibly following tree removal) that may
14 also have additional management, such as irrigation or interseeding of legumes. This Inventory includes all
15 privately-owned and federal grasslands in the conterminous United States and Hawaii, but does not include
16 approximately 50 million hectares of *Grassland Remaining Grassland* in Alaska. This leads to a discrepancy with
17 the total amount of managed area in *Grassland Remaining Grassland* (see Section 6.1 Representation of the U.S.
18 Land Base) and the grassland area included in the Inventory analysis (IPCC Source Category 4C1—Section 6.6).

19 Background on agricultural soil carbon (C) stock changes is provided in Section 6.4, *Cropland Remaining*
20 *Cropland*, and will only be summarized here. Soils are the largest pool of C in agricultural land, and also have the
21 greatest potential for longer-term storage or release of C. Biomass and dead organic matter C pools are relatively
22 small and ephemeral compared to the soil C pool, with the exception of C stored in tree and shrub biomass that
23 occurs in grasslands. The *2006 IPCC Guidelines* (IPCC 2006) recommend reporting changes in soil organic C
24 (SOC) stocks due to (1) agricultural land-use and management activities on mineral soils, and (2) agricultural land-
25 use and management activities on organic soils.⁴⁸

26 In *Grassland Remaining Grassland*, there has been considerable variation in soil C stocks between 1990 and 2015.
27 These changes are driven by variability in weather patterns and associated interaction with land management
28 activity. Moreover, changes are small on a per hectare rate across the time series even in the years with a larger total
29 change in stocks. Land use and management generally increased soil C in mineral soils for *Grassland Remaining*
30 *Grassland* between 1990 and 2012, after which the trend is reversed to a small decline in soil C. In contrast, organic
31 soils lose a relatively constant amount of C annually from 1990 through 2015. In 2015, soil C stocks decreased by
32 7.3 MMT CO₂ Eq. (2.0 MMT C), with a small loss of 1.7 MMT CO₂ Eq. (0.5 MMT C)⁴⁹ in mineral soils, but a loss
33 of 5.5 MMT CO₂ Eq. (1.5 MMT C) from organic soils (Table 6-34 and Table 6-35). The overall trend represents a
34 272 percent decline in the soil C stock change rate from a gain to a loss of soil C.

⁴⁸ CO₂ emissions associated with liming and urea fertilization are also estimated but included in the Agriculture chapter of the report.

⁴⁹ Quality control uncovered errors in the mineral soil and total net flux estimates for 2015, which will be updated following public review. Based on the revision, soil C stocks increased by 26.4 MMT CO₂ Eq. (7.2 MMT C) in 2015. The total net flux implies C sequestration of 20.9 MMT CO₂ Eq. (5.7 MMT C). The corrected overall trend is an increase in soil C stock change by 395 percent since the initial reporting year in 1990.

1 **Table 6-34: Net CO₂ Flux from Soil C Stock Changes in *Grassland Remaining Grassland* (MMT**
 2 **CO₂ Eq.)**

Soil Type	1990	2005	2011	2012	2013 ^a	2014 ^a	2015 ^a
Mineral Soils	(11.4)	(0.5)	(18.1)	(26.3)	2.2	2.3	1.7
Organic Soils	7.2	6.0	5.6	5.5	5.5	5.5	5.5
Total Net Flux	(4.2)	5.5	(12.5)	(20.8)	7.7	7.8	7.3

^a Quality control uncovered errors in the estimates of mineral soils and the total net flux for 2013, 2014 and 2015, which will be updated following public review. The corrected mineral soil estimates are (26.0), (25.9), and (26.4) MMT CO₂ Eq., respectively for 2013, 2014, 2015, and the total net flux is (20.5), (20.4) and (20.9) MMT CO₂ Eq., respectively for the three years.

Notes: Estimates after 2012 are based on NRI data from 2012 and therefore may not fully reflect changes occurring in the latter part of the time series. Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

3 **Table 6-35: Net CO₂ Flux from Soil C Stock Changes in *Grassland Remaining Grassland* (MMT**
 4 **C)**

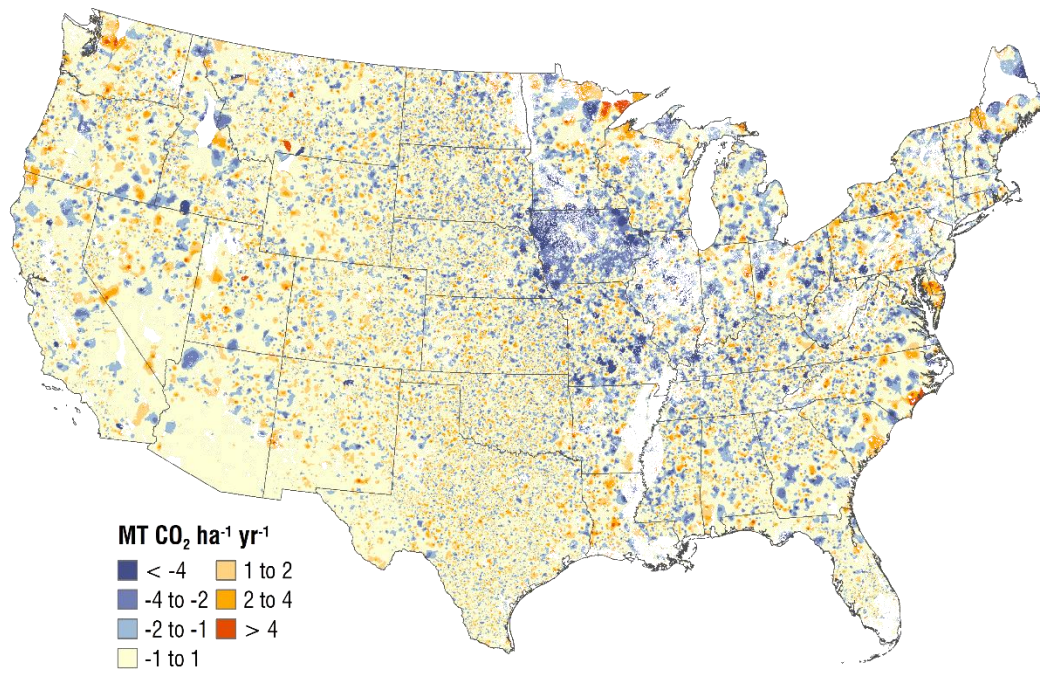

Soil Type	1990	2005	2011	2012	2013 ^a	2014 ^a	2015 ^a
Mineral Soils	(3.1)	(0.1)	(4.9)	(7.2)	0.6	0.6	0.5
Organic Soils	2.0	1.6	1.5	1.5	1.5	1.5	1.5
Total Net Flux	(1.1)	1.5	(3.4)	(5.7)	2.1	2.1	2.0

^a Quality control uncovered errors in the estimates of mineral soils and the total net flux for 2013, 2014 and 2015, which will be updated following public review. The corrected mineral soil estimates are (7.1), (7.1) and (7.2) MMT C, respectively for 2013, 2014 and 2015, and the total net flux is (5.6), (5.6) and (5.7) MMT C, respectively for the three years.

Notes: Estimates after 2012 are based on NRI data from 2012 and therefore may not fully reflect changes occurring in the latter part of the time series. Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

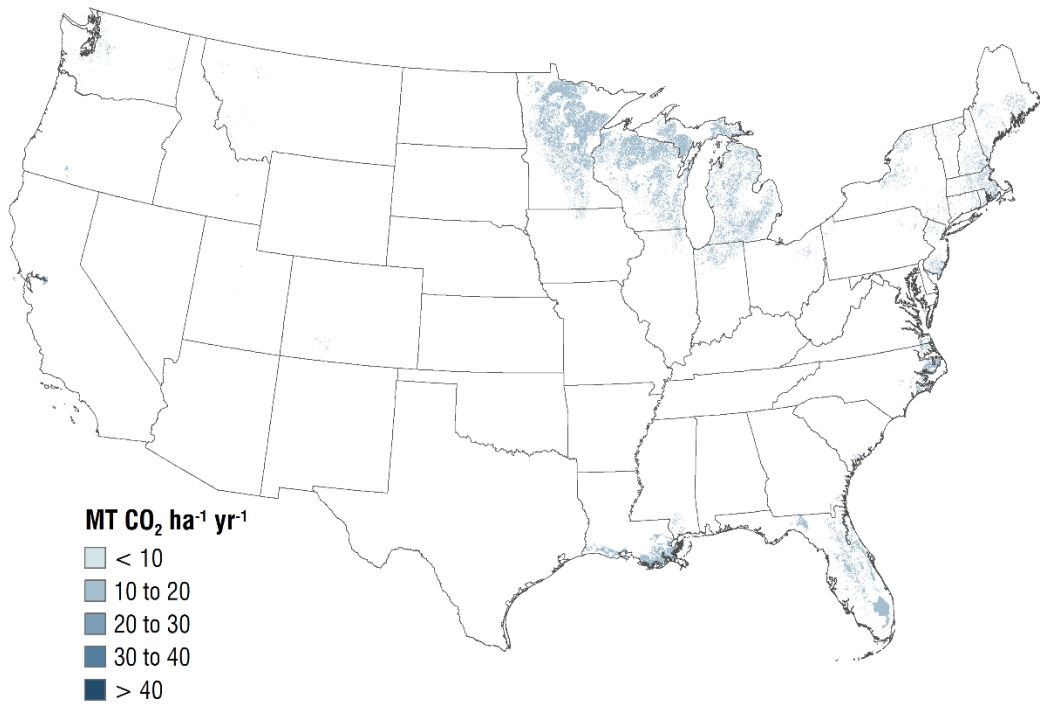

5 The spatial variability in the 2015 annual CO₂ flux associated with mineral soils is displayed in Figure 6-6 and
 6 organic soils in Figure 6-7. Although relatively small on a per-hectare basis, grassland soils gained C in isolated
 7 areas throughout the country, with a larger concentration of grasslands sequestering soil C in Iowa. For organic
 8 soils, the regions with the highest rates of emissions coincide with the largest concentrations of organic soils used
 9 for managed grassland, including the Southeastern Coastal Region (particularly Florida), upper Midwest and
 10 Northeast, and a few isolated areas along the Pacific Coast.

1 Methodology

2 The following section includes a brief description of the methodology used to estimate changes in soil C stocks for
3 *Grassland Remaining Grassland*, including: (1) agricultural land-use and management activities on mineral soils;
4 and (2) agricultural land-use and management activities on organic soils. Further elaboration on the methodologies
5 and data used to estimate stock changes from mineral and organic soils are provided in the *Cropland Remaining*
6 *Cropland* section and Annex 3.12.

7 Soil C stock changes are estimated for *Grassland Remaining Grassland* on non-federal lands according to land use
8 histories recorded in the 2012 USDA NRI survey (USDA-NRCS 2015). Land-use and some management
9 information (e.g., grass type, soil attributes, and irrigation) were originally collected for each NRI survey location on
10 a 5-year cycle beginning in 1982. In 1998, the NRI program began collecting annual data, and the annual data are
11 currently available through 2012 (USDA-NRCS 2015). NRI survey locations are classified as *Grassland Remaining*
12 *Grassland* in a given year between 1990 and 2012 if the land use had been grassland for 20 years. NRI survey
13 locations are classified according to land-use histories starting in 1979, and consequently the classifications are
14 based on less than 20 years from 1990 to 1998. This may have led to an overestimation of *Grassland Remaining*
15 *Grassland* in the early part of the time series to the extent that some areas are converted to grassland prior between
16 1971 and 1978. For federal lands, the land use history is derived from land cover changes in the National Land
17 Cover Dataset (Homer et al. 2007; Fry et al. 2011; Homer et al. 2015).

18 *Mineral Soil Carbon Stock Changes*

19 An IPCC Tier 3 model-based approach (Ogle et al. 2010) is applied to estimate C stock changes for most mineral
20 soils in *Grassland Remaining Grassland*. The C stock changes for the remaining soils are estimated with an IPCC
21 Tier 2 method (Ogle et al. 2003), including gravelly, cobbly, or shaley soils (greater than 35 percent by volume) and
22 additional stock changes associated with sewage sludge amendments.

23 **Tier 3 Approach**

24 Mineral SOC stocks and stock changes for *Grassland Remaining Grassland* are estimated using the DAYCENT
25 biogeochemical⁵⁰ model (Parton et al. 1998; Del Grosso et al. 2001, 2011), as described in *Cropland Remaining*
26 *Cropland*. The DAYCENT model utilizes the soil C modeling framework developed in the Century model (Parton et
27 al. 1987, 1988, 1994; Metherell et al. 1993), but has been refined to simulate dynamics at a daily time-step.
28 Historical land-use patterns and irrigation histories are simulated with DAYCENT based on the 2012 USDA NRI
29 survey (USDA-NRCS 2015). Frequency and rates of manure application to grassland during 1997 are estimated
30 from data compiled by the USDA Natural Resources Conservation Service (NRCS) (Edmonds, et al. 2003), and then
31 adjusted using county-level estimates of manure available for application in other years. Specifically, county-scale
32 ratios of manure available for application to soils in other years relative to 1997 are used to adjust the area amended
33 with manure (see *Cropland Remaining Cropland* section and Annex 3.12 for further details). Greater availability of
34 managed manure nitrogen (N) relative to 1997 is, thus, assumed to increase the area amended with manure, while
35 reduced availability of manure N relative to 1997 is assumed to reduce the amended area.

36 The amount of manure produced by each livestock type is calculated for managed and unmanaged waste
37 management systems based on methods described in Section 5.2 - Manure Management and Annex 3.11. Manure N
38 deposition from grazing animals (i.e., PRP manure) is an input to the DAYCENT model, and the remainder is
39 deposited on federal lands (i.e., the amount that is not included in DAYCENT simulations is assumed to be applied
40 on federal grasslands). Carbon stocks and 95 percent confidence intervals are estimated for each year between 1990
41 and 2012 using the NRI survey data, which is available through 2012. C stock change rates from 2013 to 2015 are
42 assumed to be similar to 2012 for this Inventory, but the areas may have changed through the process in which the
43 NRI survey data are reconciled with the Forest Inventory and Analysis (FIA) survey data and the National Land
44 Cover Dataset (Homer et al. 2007; Fry et al. 2011; Homer et al. 2015). This process ensures that the areas of *Forest*
45 *Land Remaining Forest Land* and *Land Converted to Forest Land* are consistent in all three datasets, and leads to
46 some modification of other lands use areas to ensure the total land area does not change. For example, if the FIA
47 estimate less *Grassland Converted to Forest Land* than the NRI, then the amount of area for this land use conversion

⁵⁰ Biogeochemical cycles are the flow of chemical elements and compounds between living organisms and the physical environment.

1 is reduced in the NRI dataset and re-classified as *Grassland Remaining Grassland* (See Section 6.1, Representation
2 of the U.S. Land Base for more information). Future Inventories will be updated with new NRI activity data when
3 the data are made available, and the time series from 2013 to 2015 will be recalculated. See the *Cropland Remaining*
4 *Cropland* section for additional discussion of the Tier 3 methodology for mineral soils.

5 **Tier 2 Approach**

6 The Tier 2 approach is based on the same methods described in the Tier 2 portion of *Cropland Remaining Cropland*
7 section for mineral soils, with the exception of the land use and management data that are used in the Inventory for
8 federal grasslands. The NRI (USDA-NRCS 2015) provides land use and management histories for all non-federal
9 lands, and is the basis for the Tier 2 analysis for these areas. However, NRI does not provide land use information
10 on federal lands. The land use data for federal lands is based on the National Land Cover Database (NLCD) (Fry et
11 al. 2011; Homer et al. 2007; Homer et al. 2015). In addition, the Bureau of Land Management (BLM) manages
12 some of the federal grasslands, and has compiled information on grassland condition through the BLM Rangeland
13 Inventory (BLM 2014). To estimate soil C stock changes from federal grasslands, rangeland conditions in the BLM
14 data are aligned with IPCC grassland management categories of nominal, moderately degraded, and severely
15 degraded in order to apply the appropriate emission factors. Further elaboration on the Tier 2 methodology and data
16 used to estimate C stock changes from mineral soils are described in Annex 3.12.

17 **Additional Mineral C Stock Change Calculations**

18 A Tier 2 method is used to adjust annual C stock change estimates for mineral soils between 1990 and 2015 to
19 account for additional C stock changes associated with sewage sludge amendments. Estimates of the amounts of
20 sewage sludge N applied to agricultural land are derived from national data on sewage sludge generation,
21 disposition, and N content. Although sewage sludge can be added to land managed for other land uses, it is assumed
22 that agricultural amendments only occur in *Grassland Remaining Grassland*. Cropland is not likely to be amended
23 with sewage sludge due to the high metal content and other pollutants in human waste. Total sewage sludge
24 generation data for 1988, 1996, and 1998, in dry mass units, are obtained from EPA (1999) and estimates for 2004
25 are obtained from an independent national biosolids survey (NEBRA 2007). These values are linearly interpolated to
26 estimate values for the intervening years, and linearly extrapolated to estimate values for years since 2004. N
27 application rates from Kellogg et al. (2000) are used to determine the amount of area receiving sludge amendments.
28 The soil C storage rate is estimated at 0.38 metric tons C per hectare per year for sewage sludge amendments to
29 grassland as described above. The stock change rate is based on country-specific factors and the IPCC default
30 method (see Annex 3.12 for further discussion).

31 **Organic Soil Carbon Stock Changes**

32 Annual C emissions from drained organic soils in *Grassland Remaining Grassland* are estimated using the Tier 2
33 method provided in IPCC (2006), which utilizes U.S.-specific C loss rates (Ogle et al. 2003) rather than default
34 IPCC rates. For more information, see the *Cropland Remaining Cropland* section for organic soils.

35 **Uncertainty and Time-Series Consistency**

36 Uncertainty analysis for mineral soil C stock changes using the Tier 3 and Tier 2 methodologies are based on a
37 Monte Carlo approach that is described in the *Cropland Remaining Cropland* section. The uncertainty for annual C
38 emission estimates from drained organic soils in *Grassland Remaining Grassland* is estimated using a Monte Carlo
39 approach, which is also described in the *Cropland Remaining Cropland* section.

40 Uncertainty estimates are presented in Table 6-36 for each subsource (i.e., mineral soil C stocks and organic soil C
41 stocks) and the method applied in the inventory analysis (i.e., Tier 2 and Tier 3). Uncertainty estimates from the Tier
42 2 and 3 approaches are combined using the simple error propagation methods provided by the IPCC (2006), i.e., by
43 taking the square root of the sum of the squares of the standard deviations of the uncertain quantities. The combined
44 uncertainty for soil C stocks in *Grassland Remaining Grassland* ranges from -461 percent below to 465 percent

1 above the 2015 stock change estimate of 7.3 MMT CO₂ Eq.⁵¹ The large relative uncertainty is due to the almost zero
 2 level of change in soil C for 2015, particularly in the land base for *Grassland Remaining Grassland* included in the
 3 Tier 2 analysis.

4 **Table 6-36: Approach 2 Quantitative Uncertainty Estimates for C Stock Changes Occurring**
 5 **Within *Grassland Remaining Grassland* (MMT CO₂ Eq. and Percent)**

Source	2015 Flux Estimate ^a (MMT CO ₂ Eq.)	Uncertainty Range Relative to Flux Estimate ^{a,b} (MMT CO ₂ Eq.) (%)			
		Lower Bound	Upper Bound	Lower Bound	Upper Bound
Mineral Soil C Stocks Grassland Remaining Grassland, Tier 3 Methodology	3.9	(28.0)	35.8	-823%	823%
Mineral Soil C Stocks: Grassland Remaining Grassland, Tier 2 Methodology	(0.7)	(10.3)	9.6	-1,387%	1,490%
Mineral Soil C Stocks: Grassland Remaining Grassland, Tier 2 Methodology (Change in Soil C due to Sewage Sludge Amendments)	(1.5)	(2.2)	(0.7)	-50%	50%
Organic Soil C Stocks: Grassland Remaining Grassland, Tier 2 Methodology	5.5	3.0	8.9	-46%	61%
Combined Uncertainty for Flux Associated with Agricultural Soil Carbon Stock Change in Grassland Remaining Grassland	7.3	(26.2)	41.0	-461%	465%

^a Quality control uncovered errors in the estimate and uncertainty for 2015, which will be updated following public review. The corrected Tier 3 mineral soil C stock change is (24.2) MMT CO₂ Eq., with an uncertainty ranging from -150 percent to 150 percent. The corrected combined flux estimate for 2015 is (20.9) MMT CO₂ Eq., with an uncertainty ranging from -180 percent to 182 percent.

^b Range of C stock change estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Notes: Totals may not sum due to independent rounding. Parentheses indicate negative values or net sequestration.

6 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 7 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 8 above.

9 Uncertainty is also associated with a lack of reporting on biomass and litter C stock changes and non-CO₂
 10 greenhouse gas emissions from grassland fires. Biomass C stock changes may be significant for managed grasslands
 11 with woody encroachment despite not having attained enough tree cover to be considered forest lands. In addition,
 12 changes in dead organic matter C stocks are assumed to be negligible in grasslands over annual time frames,
 13 although there are certainly significant changes at sub-annual time scales across seasons.

14 QA/QC and Verification

15 See the QA/QC and Verification section in *Cropland Remaining Cropland*.

16 Recalculations Discussion

17 Methodological recalculations in the current Inventory are associated with the following improvements, including
 18 (1) driving the DAYCENT simulations with updated input data for land use and management from the National
 19 Resources Inventory from 1979 through 2012; (2) increasing the number of experimental study sites used to
 20 quantify model uncertainty; (3) DAYCENT model development to improve the simulation of soil temperature; and

⁵¹ Quality control uncovered errors in the estimate and uncertainty for 2015, which will be updated following public review. Based on the revision, soil C stocks increased by 20.9 MMT CO₂ Eq. in 2015, with an uncertainty ranging from -180 percent below to 182 percent above the estimate.

(4) improvements in the cropping and land use histories that are simulated in DAYCENT between 1950 and 1979 that generate initial values for the model state variables, including the initial soil organic C stock values. The differences in SOC stock changes with the recalculations are highly variable across the time series, with an increase in some years and a decrease in other years. On average, the SOC stock changes decreased by 0.8 MMT CO₂ Eq. compared to the previous Inventory, but with the large variability, there is an 83 percent decrease on average in the reported soil C stock changes.⁵²

7 Planned Improvements

8 Grasslands in Alaska are not currently included in the Inventory. This is a significant planned improvement and
 9 estimates are expected to be available for the 1990 through 2017 Inventory (2019 submission to the UNFCCC).
 10 Another key planned improvement is to estimate woody biomass C stock changes for grasslands (See Box 6-6). For
 11 information about other improvements, see the Planned Improvements section in *Cropland Remaining Cropland*.

13 Box 6-6: Grassland Woody Biomass Analysis

14 An initial analysis of woodland biomass has been conducted for regions in the western United States. Woodlands are
 15 areas with trees in a matrix of grass vegetation that does not reach the thresholds for tree cover, diameter at breast
 16 height, and/or tree height to be considered forest land. For this pilot effort, carbon stock densities and stock changes
 17 are estimated using woodland plots in the Forest Inventory and Analysis (FIA) database. The full set of woodland
 18 plots cover 12 states in the western United States, and include two FIA forest type groups, pinyon-juniper and
 19 woodland hardwoods. The results suggest that woodlands are sequestering approximately 20 MMT CO₂ Eq. in
 20 biomass, dead wood, and litter pools. The analysis will be expanded to the entire time series and reported in a future
 21 Inventory.

22

**23 Non-CO₂ Emissions from Grassland Fires (IPCC Source
 24 Category 3C1c)**

25 Fires are common in grasslands, and are thought to have been a key feature shaping the evolution of the grassland
 26 vegetation in North America (Daubenmire 1968; Anderson 2004). Fires can occur naturally through lightning
 27 strikes, but are also an important management practice to remove standing dead and improve forage for grazing
 28 livestock. Woody and herbaceous biomass will be oxidized in a fire, although we are focused primarily on
 29 herbaceous biomass in this section.⁵³ Biomass burning emits a variety of trace gases including non-CO₂ greenhouse
 30 gases, CH₄ and N₂O, as well as CO and NO_x that can become greenhouse gases when they react with other gases in
 31 the atmosphere (Andreae and Merlet 2001). IPCC (2006) recommends reporting non-CO₂ greenhouse gas emissions
 32 from all wildfires and prescribed burning occurring in managed grasslands.

33 Biomass burning in grassland of the United States is a relatively small source of emissions, but it has increased by
 34 424 percent since 1990. In 2015, CH₄ and N₂O emissions from biomass burning in grasslands were 0.4 MMT CO₂
 35 Eq. (16 kt) and 0.4 MMT CO₂ Eq. (1 kt), respectively. Annual emissions from 1990 to 2015 have averaged
 36 approximately 0.3 MMT CO₂ Eq. (12 kt) of CH₄ and 0.3 MMT CO₂ Eq. (1 kt) of N₂O (see Table 6-37 and Table
 37 6-38).

38 Table 6-37: CH₄ and N₂O Emissions from Biomass Burning in Grassland (MMT CO₂ Eq.)

39

	1990	2005	2011	2012	2013	2014	2015
--	------	------	------	------	------	------	------

⁵² Quality control uncovered errors in the estimate and uncertainty for 2013, 2014, 2015, which will be updated following public review. These corrections impact the comparison between the prior and current Inventories in the Recalculation Discussion, which will also be updated after public review.

⁵³ A planned improvement is underway to incorporate woodland tree biomass into the inventory.

CH ₄	0.1	0.3	0.8	0.6	0.2	0.4	0.4
N ₂ O	0.1	0.3	0.9	0.6	0.2	0.4	0.4
Total Net Flux	0.2	0.7	1.7	1.2	0.4	0.8	0.8

Notes: Estimate for 2015 is based on the 2014 data, and therefore may not fully reflect changes occurring in the last year of the time series. Burned area in 2015 was assumed to be the same as 2014 because MODIS data were not available and processed in time for this Inventory. Totals may not sum due to independent rounding.

Table 6-38: CH₄, N₂O, CO, and NO_x Emissions from Biomass Burning in Grassland (kt)

+ Does not exceed 0.5 kt

Notes: Estimate for 2015 is based on the 2014 data, and therefore may not fully reflect changes occurring in the last year of the time series. Burned area in 2015 was assumed to be the same as 2014 because MODIS data were not available and processed in time for this Inventory. Totals may not sum due to independent rounding.

Methodology

The following section includes a description of the methodology used to estimate non-CO₂ greenhouse gas emissions from biomass burning in grassland, including (1) determination of the land base that is classified as managed grassland; (2) assessment of managed grassland area that is burned each year, and (3) estimation of emissions resulting from the fires. For this Inventory, the IPCC Tier 1 method is applied to estimate non-CO₂ greenhouse gas emissions from biomass burning in grassland (IPCC 2006).

The land area designated as managed grassland is based primarily on the 2012 National Resources Inventory (NRI) (Nusser and Goebel 1997; USDA 2015). NRI has survey locations across the entire United States, but does not classify land use on federally-owned areas. These survey locations are designated as grassland using land cover data from the National Land Cover Dataset (NLCD) (Fry et al. 2011; Homer et al. 2007; Homer et al. 2015) (see Section 0 Representation of the U.S. Land Base).

The area of biomass burning in grasslands (*Grassland Remaining Grassland* and *Land Converted to Grassland*) is determined using 30-m fire data from the Monitoring Trends in Burn Severity (MTBS) program for 1990 through 2014.⁵⁴ NRI survey locations on grasslands are designated as burned in a year if there is a fire within a 500 m of the survey point. The area of biomass burning is estimated from the NRI spatial weights and aggregated to the country (Table 6-39).

Table 6-39: Thousands of Grassland Hectares Burned Annually

Year	Thousand Hectares
1990	317
2005	1,343
2011	3,356
2012	2,464
2013	815
2014	1,659
2015	1,659

Notes: Burned area in 2015 was assumed to be the same as 2014 because MTBS data were

⁵⁴ See <<http://www.mtbs.gov/nationalregional/burnedarea.html>>.

not available and processed in time for this Inventory. The burned area will be updated in the next Inventory.

To estimate the amount of combusted biomass, the total area of grassland burned is multiplied by the IPCC default factor for grassland biomass (4.1 tonnes dry matter per ha) (IPCC 2006). A combustion factor of 1 is assumed in this Inventory, and the resulting biomass estimate is multiplied by the IPCC default grassland emission factors for CH₄ (2.3 g CH₄ per kg dry matter), N₂O (0.21 g CH₄ per kg dry matter), CO (65 g CH₄ per kg dry matter) and NO_x (3.9 g CH₄ per kg dry matter) (IPCC 2006). The Tier 1 analysis is implemented in the Agriculture and Land Use National Greenhouse Gas Inventory (ALU) software (Ogle et al. 2016).⁵⁵

Uncertainty and Time-Series Consistency

The results of the Approach 2 Monte Carlo uncertainty analysis are summarized in Table 6-40. Methane emissions from Biomass Burning in Grassland for 2015 is estimated to be between 0 and 1.2 MMT CO₂ Eq. at a 95 percent confidence level. This indicates a range of 100 percent below and 209 percent above the 2015 emission estimate of 0.4 MMT CO₂ Eq. Nitrous oxide emissions are estimated to be between 0 and 1.4 MMT CO₂ Eq., or approximately 100 percent below and 229 percent above the 2015 emission estimate of 0.4 MMT CO₂ Eq.

Table 6-40: Uncertainty Estimates for Non-CO₂ Greenhouse Gas Emissions from Biomass Burning in Grassland (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Grassland Burning	CH ₄	0.4	0.0	1.2	-100%	209%
Grassland Burning	N ₂ O	0.4	0.0	1.4	-100%	229%

^a Range of flux estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Note: Quality control measures are still underway and uncertainty estimates will be finalized after the public review.

Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

Uncertainty is also associated with lack of reporting of emissions from biomass burning in grassland of Alaska. Grassland burning emissions could be relatively large in this region of the United States, and therefore extending this analysis to include Alaska is a planned improvement for the Inventory. There is also uncertainty due to lack of reporting combustion of woody biomass, and this is another planned improvement.

QA/QC and Verification

Quality control measures included checking input data, model scripts, and results to ensure data are properly handled throughout the inventory process. Inventory reporting forms and text are reviewed and revised as needed to correct transcription errors. Quality control identified problems with cell references in the spreadsheets, which have been corrected.

Planned Improvements

Two planned improvements have been identified for this source category, including a) incorporation of country-specific grassland biomass factors, and b) extending the analysis to include Alaska. In the current Inventory, biomass factors are based on a global default for grasslands that is provided by the IPCC (2006). There is considerable variation in grassland biomass, however, which would affect the amount of biomass combusted in a

⁵⁵ See <<http://www.nrel.colostate.edu/projects/ALUsoftware/>>.

1 fire. Alaska has an extensive area of grassland and includes tundra vegetation, although some of the areas are not
2 managed. There has been an increase in fire frequency in boreal forest of the region (Chapin et al. 2008), and this
3 may have led to an increase in burning of neighboring grassland areas. There is also an effort under development to
4 incorporate grassland fires into DAYCENT model simulations. Both improvements are expected to reduce
5 uncertainty and lead to more accurate estimates of non-CO₂ greenhouse gas emissions from grassland burning.

6 6.7 Land Converted to Grassland (IPCC Source 7 Category 4C2)

8 *Land Converted to Grassland* includes all grassland in an Inventory year that had been in another land use(s) during
9 the previous 20 years (USDA-NRCS 2015).⁵⁶ For example, cropland or forest land converted to grassland during
10 the past 20 years would be reported in this category. Recently-converted lands are retained in this category for 20
11 years as recommended by IPCC (2006). Grassland includes pasture and rangeland that are used primarily but not
12 exclusively for livestock grazing. Rangelands are typically extensive areas of native grassland that are not
13 intensively managed, while pastures are typically seeded grassland (possibly following tree removal) that may also
14 have additional management, such as irrigation or interseeding of legumes. This Inventory includes all grasslands in
15 the conterminous United States and Hawaii, but does not include *Land Converted to Grassland* in Alaska.
16 Consequently there is a discrepancy between the total amount of managed area for *Land Converted to Grassland*
17 (see Section 6.1 Representation of the U.S. Land Base) and the grassland area included in the inventory analysis
18 (IPCC Source Category 4C2—Section 6.7).

19 Land-use change can lead to large losses of C to the atmosphere, particularly conversions from forest land
20 (Houghton et al. 1983). Moreover, conversion of forest to another land use (i.e., deforestation) is one of the largest
21 anthropogenic sources of emissions to the atmosphere globally (Schimel 1995), although this source may be
22 declining according to a recent assessment (Tubiello et al. 2015).

23 IPCC (2006) recommends reporting changes in biomass, dead organic matter, and soil organic C (SOC) stocks due
24 to land use change.⁵⁷ All soil C stock changes are estimated and reported for *Land Converted to Grassland*, but
25 there is limited reporting of other pools in this Inventory. Loss of aboveground and belowground biomass, dead
26 wood and litter C from *Forest Land Converted to Grassland* is reported, but biomass and dead organic matter C
27 stock changes are not estimated for other land use conversions to grassland.⁵⁸

28 Land use and management of mineral soils in *Land Converted to Grassland* led to an increase in soil C stocks
29 between 1990 and 2015 (see Table 6-41 and Table 6-42). The average soil C stock change for mineral soils between
30 1990 and 2015 sequestered 11.3 MMT CO₂ Eq. from the atmosphere (3.1 MMT C).⁵⁹ In contrast, over the same
31 period, drainage of organic soils for grassland management led to CO₂ emissions to the atmosphere of 1.3 MMT
32 CO₂ Eq. (0.4 MMT C). In addition, aboveground biomass, belowground biomass, dead wood and litter C losses
33 from *Forest Land Converted to Grassland* led to CO₂ emissions to the atmosphere of 184.9, 24.0, 46.3 and 50.0
34 MMT CO₂ Eq. (50.4, 6.5, 12.6 and 13.6 MMT C), respectively, in 2015. The total net C stock change in 2015 for

⁵⁶ NRI survey locations are classified according to land-use histories starting in 1979, and consequently the classifications are based on less than 20 years from 1990 to 2001. This may have led to an underestimation of *Land Converted to Grassland* in the early part of the time series to the extent that some areas are converted to grassland between 1971 and 1978.

⁵⁷ CO₂ emissions associated with liming and urea fertilization are also estimated but included in the Agriculture chapter of the report.

⁵⁸ Changes in biomass C stocks are not currently reported for other conversions to grassland (other than forest land), but this is a planned improvement for a future inventory. Note: changes in dead organic matter are assumed to negligible for other land use conversions (i.e., other than forest land) to grassland based on the Tier 1 method in IPCC (2006).

⁵⁹ Quality control uncovered errors in the mineral soil C and total net flux estimates for 2015, which will be updated following public review. Based on the revisions, mineral soil C stocks increased by 13.6 MMT CO₂ Eq. (3.7 MMT C) in 2015. The total net flux represents a loss of 293.2 MMT CO₂ Eq. (80.0 MMT C) from *Land Converted to Grassland*.

1 *Land Converted to Grassland* is estimated as a loss of 294.2 MMT CO₂ Eq. (80.2 MMT C), which is a 20 percent
 2 increase in emissions compared to the emissions in the initial reporting year of 1990.

^a Quality control uncovered errors in the estimates for 2013, 2014 and 2015 for mineral soils in *Cropland Converted to Grassland*, Total Mineral Soil Flux and the Total Net Flux, which will be updated following public review. The corrected mineral soil estimates for *Cropland Converted to Grassland* are (3.4), (3.4) and (3.4) MMT C, respectively for 2013, 2014, 2015; the total mineral net flux is (3.7), (3.7) and (3.7) MMT C, respectively for the three years; and the total net flux for *Land Converted to Grassland* is 80.0, 80.0 and 80.0 MMT C, respectively for the three years.

Notes: Estimates after 2012 are based on NRI data from 2012 and therefore may not fully reflect changes occurring in the latter part of the time series. Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

1 Methodology

2 The following section includes a description of the methodology used to estimate changes in biomass and soil C
3 stocks for *Land Converted to Grassland*, including: (1) loss of aboveground and belowground biomass, dead wood
4 and litter C with conversion of forest lands to grassland; (2) agricultural land-use and management activities on
5 mineral soils; and (3) agricultural land-use and management activities on organic soils.

6 Biomass, Dead Biomass and Litter Carbon Stock Changes

7 A Tier 2 method is applied to estimate aboveground biomass C stock changes for *Forest Land Converted to*
8 *Grassland*. For this method, forest land conversions to grasslands were identified in each state and C density
9 estimates were compiled by state for aboveground biomass, belowground biomass, dead wood, and litter for
10 grasslands (assumed to be zero since no reference biomass C density estimates exist) and forest land use categories.
11 The difference between the stocks is reported as the stock change under the assumption that the change occurred in
12 the year of the conversion. Reference C density estimates (i.e., aboveground biomass, belowground biomass, dead
13 wood, and litter) for the forest land use have been estimated from data in the Forest Inventory and Analysis (FIA)
14 program within the USDA Forest Service (USDA Forest Service 2015). If FIA plots include data on individual trees,
15 aboveground and belowground C density estimates are based on Woodall et al. (2011). Aboveground and
16 belowground biomass estimates also include live understory which is a minor component of biomass defined as all
17 biomass of undergrowth plants in a forest, including woody shrubs and trees less than 2.54 cm dbh. For this
18 Inventory, it was assumed that 10 percent of total understory C mass is belowground (Smith et al. 2006). Estimates
19 of C density are based on information in Birdsey (1996) and biomass estimates from Jenkins et al. (2003). If FIA
20 plots include data on standing dead trees, standing dead tree C density is estimated following the basic method
21 applied to live trees (Woodall et al. 2011) with additional modifications to account for decay and structural loss
22 (Domke et al. 2011; Harmon et al. 2011). If FIA plots include data on downed dead wood, downed dead wood C
23 density is estimated based on measurements of a subset of FIA plots for downed dead wood (Domke et al. 2013;
24 Woodall and Monleon 2008). Downed dead wood is defined as pieces of dead wood greater than 7.5 cm diameter, at
25 transect intersection, that are not attached to live or standing dead trees. This includes stumps and roots of harvested
26 trees. To facilitate the downscaling of downed dead wood C estimates from the state-wide population estimates to
27 individual plots, downed dead wood models specific to regions and forest types within each region are used. Litter C

1 is the pool of organic C (also known as duff, humus, and fine woody debris) above the mineral soil and includes
2 woody fragments with diameters of up to 7.5 cm. A subset of FIA plots are measured for litter C. If FIA plots
3 include litter material, a modeling approach using litter C measurements from FIA plots is used to estimate litter C
4 density (Domke et al. 2016). See Annex 3.13 for more information about reference C density estimates for forest
5 land.

6 **Soil Carbon Stock Changes**

7 Soil C stock changes are estimated for *Land Converted to Grassland* according to land-use histories recorded in the
8 2012 USDA NRI survey for non-federal lands (USDA-NRCS 2015). Land use and some management information
9 (e.g., crop type, soil attributes, and irrigation) were originally collected for each NRI survey locations on a 5-year
10 cycle beginning in 1982. In 1998, the NRI Program began collecting annual data, and the annual data are currently
11 available through 2012 (USDA-NRCS 2015). NRI survey locations are classified as *Land Converted to Grassland*
12 in a given year between 1990 and 2012 if the land use is grassland but had been classified as another use during the
13 previous 20 years. NRI survey locations are classified according to land-use histories starting in 1979, and
14 consequently the classifications are based on less than 20 years from 1990 to 1998. This may have led to an
15 underestimation of *Land Converted to Grassland* in the early part of the time series to the extent that some areas are
16 converted to grassland between 1971 and 1978. For federal lands, the land use history is derived from land cover
17 changes in the National Land Cover Dataset (Homer et al. 2007; Fry et al. 2011; Homer et al. 2015).

18 *Mineral Soil Carbon Stock Changes*

19 An IPCC Tier 3 model-based approach (Ogle et al. 2010) is applied to estimate C stock changes for *Land Converted*
20 *to Grassland* on most mineral soils. C stock changes on the remaining soils are estimated with an IPCC Tier 2
21 approach (Ogle et al. 2003), including prior cropland used to produce vegetables, tobacco, and
22 perennial/horticultural crops; land areas with very gravelly, cobbly, or shaley soils (greater than 35 percent by
23 volume); and land converted to grassland from another land use other than cropland.

24 *Tier 3 Approach.* Mineral SOC stocks and stock changes are estimated using the DAYCENT biogeochemical⁶⁰
25 model (Parton et al. 1998; Del Grosso et al. 2001, 2011). The DAYCENT model utilizes the soil C modeling
26 framework developed in the Century model (Parton et al. 1987, 1988, 1994; Metherell et al. 1993), but has been
27 refined to simulate dynamics at a daily time-step. Historical land-use patterns and irrigation histories are simulated
28 with DAYCENT based on the 2012 USDA NRI survey (USDA-NRCS 2015). C stocks and 95 percent confidence
29 intervals are estimated for each year between 1990 and 2012, but C stock changes from 2013 to 2015 are assumed to
30 be similar to 2012. Future inventories will be updated with new activity data when the data are made available, and
31 the time series will be recalculated (See Planned Improvements section in *Cropland Remaining Cropland*). See the
32 *Cropland Remaining Cropland* section and Annex 3.12 for additional discussion of the Tier 3 methodology for
33 mineral soils.

34 *Tier 2 Approach.* For the mineral soils not included in the Tier 3 analysis, SOC stock changes are estimated using a
35 Tier 2 Approach for *Land Converted to Grassland* as described in the Tier 2 Approach for mineral soils in the
36 *Grassland Remaining Grassland* section.

37 *Organic Soil Carbon Stock Changes*

38 Annual C emissions from drained organic soils in *Land Converted to Grassland* are estimated using the Tier 2
39 method provided in IPCC (2006), with U.S.-specific C loss rates (Ogle et al. 2003) as described in the *Cropland*
40 *Remaining Cropland* section for organic soils.

41 **Uncertainty and Time-Series Consistency**

42 The uncertainty analysis for biomass, dead wood and litter C losses with *Forest Land Converted to Grassland* is
43 conducted in the same way as the uncertainty assessment for forest ecosystem C flux in the *Forest Land Remaining*

⁶⁰ Biogeochemical cycles are the flow of chemical elements and compounds between living organisms and the physical environment.

1 *Forest Land* category. Sample and model-based error are combined using simple error propagation methods
 2 provided by the IPCC (2006). For additional details see the Uncertainty Analysis in Annex 3.13. The uncertainty
 3 analyses for mineral soil C stock changes using the Tier 3 and Tier 2 methodologies are based on a Monte Carlo
 4 approach that is described in the *Cropland Remaining Cropland* section. The uncertainty for annual C emission
 5 estimates from drained organic soils in *Land Converted to Grassland* is estimated using a Monte Carlo approach,
 6 which is also described in the *Cropland Remaining Cropland* section.

7 Uncertainty estimates are presented in Table 6-43 for each subsource (i.e., biomass C stocks, mineral soil C stocks
 8 and organic soil C stocks) and the method applied in the inventory analysis (i.e., Tier 2 and Tier 3). Uncertainty
 9 estimates from the Tier 2 and 3 approaches are combined using the simple error propagation methods provided by
 10 the IPCC (2006), i.e., by taking the square root of the sum of the squares of the standard deviations of the uncertain
 11 quantities. The combined uncertainty for total C stocks in *Land Converted to Grassland* ranges from 20 percent
 12 below to 20 percent above the 2015 stock change estimate of 294.2 MMT CO₂ Eq.⁶¹

13 **Table 6-43: Approach 2 Quantitative Uncertainty Estimates for Soil C Stock Changes**
 14 **occurring within *Land Converted to Grassland* (MMT CO₂ Eq. and Percent)**

Source	2015 Flux Estimate ^a (MMT CO ₂ Eq.)	Uncertainty Range Relative to Flux Estimate ^{a,b} (%)

Mineral Soil C Stocks: Tier 3	(10.2)	(18.9)	(1.5)	-86%	86%
Mineral Soil C Stocks: Tier 2	(2.4)	(3.5)	(1.4)	-44%	41%
Organic Soil C Stocks: Tier 2	1.6	1.1	2.4	-35%	49%

⁶¹ Quality control uncovered errors in the estimate and uncertainty for 2015, which will be updated following public review. The corrected total stock declined by 293.2 MMT CO₂ Eq. in 2015, with an uncertainty ranging from -20 percent below to 20 percent above the estimate.

+ Absolute value does not exceed 0.05 MMT CO₂ Eq.

^a Quality control uncovered errors in the 2015 estimates for mineral soils in *Cropland Converted to Grassland* for Tier 3, Total *Cropland Converted to Grassland*, Total Mineral Soil Flux for Tier 3, and the Total Net Flux for *Land Converted to Grassland*, which will be updated following public review. The corrected estimate for mineral soils in *Cropland Converted to Grassland* for Tier 3 is (11.2) MMT CO₂ Eq. for 2015 with an uncertainty ranging from -74 percent to 74 percent; *Cropland Converted to Grassland* is (11.2) MMT CO₂ Eq. for 2015 with an uncertainty ranging from -74 percent to 74 percent; the total Tier 3 mineral stock change is also (11,2) MMT CO₂ Eq. with uncertainty ranging from -74 percent to 74 percent; and the total net flux for *Land Converted to Grassland* is 293 MMT CO₂ Eq. with uncertainty ranging from -20 percent to 20 percent.

^b Range of C stock change estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Notes: Totals may not sum due to independent rounding. Parentheses indicate negative values or net sequestration.

1 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
2 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
3 above.

4 Uncertainty is also associated with a lack of reporting on biomass and dead organic matter C stock changes for *Land*
5 *Converted to Grassland* with the exception of forest land conversion. Biomass C stock changes may be significant
6 for managed grasslands with woody encroachment despite not having attained enough tree cover to be considered
7 forest lands. Changes in dead organic matter C stocks are assumed to be negligible with conversion of land to
8 grasslands with the exception of forest lands, which are included in this analysis. This assumption will be further
9 explored in a future Inventory.

10 QA/QC and Verification

11 See the QA/QC and Verification section in *Cropland Remaining Cropland*.

12 Recalculations Discussion

13 Methodological recalculations in the current Inventory are associated with the following improvements, including:
14 (1) driving the DAYCENT simulations with updated input data for land use and management from the National
15 Resources Inventory extending the time series through 2012; (2) modifying the number of experimental study sites
16 used to quantify model uncertainty; (3) DAYCENT model development to improve the simulation of soil
17 temperature; (4) improvements in the cropping and land use histories that are simulated in DAYCENT between
18 1950 and 1979 that generate initial values for the model state variables, including the initial soil organic C stock
19 values; and (5) incorporating belowground biomass, dead wood and litter C stock losses for *Forest Land Converted*
20 *to Grassland*. As a result of these improvements to the Inventory, changes in stocks declined, relative to the previous
21 report, by an average of 272.9 MMT CO₂ Eq. annually over the time series. This represents a 673 percent increase in
22 the losses of carbon from *Land Converted to Grassland* compared to the previous Inventory.⁶² This change is due to
23 a larger amount of aboveground biomass C that is lost from *Forest Land Converted to Grasslands*, in addition to
24 inclusion of belowground biomass, dead wood and litter C stock changes in this Inventory.

25 Planned Improvements

26 Soil C stock changes with land use conversion from forest land to grassland are undergoing further evaluation to
27 ensure consistency in the time series. Different methods are used to estimate soil C stock changes in forest land and
28 grasslands, and while the areas have been reconciled between these land uses, there has been limited evaluation of
29 the consistency in C stock changes with conversion from forest land to grassland. In addition, biomass C stock
30 changes will be estimated for *Cropland Converted to Grassland*, and other land use conversions to grassland, to the
31 extent that data are available. One additional planned improvement for the *Land Converted to Grassland* category is

⁶² Quality control uncovered errors in the estimate and uncertainty for 2013, 2014, 2015, which will be updated following public review. These corrections impact the comparison between the prior and current Inventories in the Recalculation Discussion, which will also be updated after public review.

1 to develop an inventory of C stock changes for grasslands in Alaska. For information about other improvements, see
2 the Planned Improvements section in *Cropland Remaining Cropland* and *Grassland Remaining Grassland*.

3 **6.8 Wetlands Remaining Wetlands (IPCC** 4 **Source Category 4D1)**

5 *Wetlands Remaining Wetlands* includes all wetland in an Inventory year that had been classified as wetland for the
6 previous 20 years, and in this Inventory includes Peatlands and Coastal Wetlands.

7 **Peatlands Remaining Peatlands**

8 **Emissions from Managed Peatlands**

9 Managed peatlands are peatlands which have been cleared and drained for the production of peat. The production
10 cycle of a managed peatland has three phases: land conversion in preparation for peat extraction (e.g., clearing
11 surface biomass, draining), extraction (which results in the emissions reported under *Peatlands Remaining*
12 *Peatlands*), and abandonment, restoration, or conversion of the land to another use.

13 CO₂ emissions from the removal of biomass and the decay of drained peat constitute the major greenhouse gas flux
14 from managed peatlands. Managed peatlands may also emit CH₄ and N₂O. The natural production of CH₄ is largely
15 reduced but not entirely shut down when peatlands are drained in preparation for peat extraction (Strack et al. 2004
16 as cited in the *2006 IPCC Guidelines*). Drained land surface and ditch networks contribute to the CH₄ flux in
17 peatlands managed for peat extraction. Methane emissions were considered insignificant under IPCC Tier 1
18 methodology (IPCC 2006), but are included in the emissions estimates for *Peatlands Remaining Peatlands*
19 consistent with the *2013 Supplement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories:*
20 *Wetlands* (IPCC 2013). Nitrous oxide emissions from managed peatlands depend on site fertility. In addition,
21 abandoned and restored peatlands continue to release greenhouse gas emissions. Although methodologies are
22 provided for rewetted organic soils (which includes rewetted/restored peatlands) in IPCC (2013) guidelines,
23 information on the areal extent of rewetted/restored peatlands in the United States is currently unavailable. This
24 Inventory estimates CO₂, N₂O, and CH₄ emissions from peatlands managed for peat extraction in accordance with
25 IPCC (2006 and 2013) guidelines.

26 **CO₂, N₂O, and CH₄ Emissions from Peatlands Remaining Peatlands**

27 IPCC (2013) recommends reporting CO₂, N₂O, and CH₄ emissions from lands undergoing active peat extraction
28 (i.e., *Peatlands Remaining Peatlands*) as part of the estimate for emissions from managed wetlands. Peatlands occur
29 where plant biomass has sunk to the bottom of water bodies and water-logged areas and exhausted the oxygen
30 supply below the water surface during the course of decay. Due to these anaerobic conditions, much of the plant
31 matter does not decompose but instead forms layers of peat over decades and centuries. In the United States, peat is
32 extracted for horticulture and landscaping growing media, and for a wide variety of industrial, personal care, and
33 other products. It has not been used for fuel in the United States for many decades. Peat is harvested from two types
34 of peat deposits in the United States: sphagnum bogs in northern states (e.g., Minnesota) and wetlands in states
35 further south (e.g., Florida). The peat from sphagnum bogs in northern states, which is nutrient poor, is generally
36 corrected for acidity and mixed with fertilizer. Production from more southerly states is relatively coarse (i.e.,
37 fibrous) but nutrient rich.

38 IPCC (2006 and 2013) recommend considering both on-site and off-site emissions when estimating CO₂ emissions
39 from *Peatlands Remaining Peatlands* using the Tier 1 approach. Current methodologies estimate only on-site N₂O
40 and CH₄ emissions, since off-site N₂O estimates are complicated by the risk of double-counting emissions from
41 nitrogen fertilizers added to horticultural peat, and off-site CH₄ emissions are not relevant given the non-energy uses
42 of peat, so methodologies are not provided in IPCC (2013) guidelines. On-site emissions from managed peatlands
43 occur as the land is cleared of vegetation and the underlying peat is exposed to sun and weather. As this occurs,

1 some peat deposit is lost and CO₂ is emitted from the oxidation of the peat. Since N₂O emissions from saturated
 2 ecosystems tend to be low unless there is an exogenous source of nitrogen, N₂O emissions from drained peatlands
 3 are dependent on nitrogen mineralization and therefore on soil fertility. Peatlands located on highly fertile soils
 4 contain significant amounts of organic nitrogen in inactive form. Draining land in preparation for peat extraction
 5 allows bacteria to convert the nitrogen into nitrates which leach to the surface where they are reduced to N₂O, and
 6 contributes to the activity of methanogens and methanotrophs (Blodau 2002; Treat et al. 2007 as cited in IPCC
 7 2013). Drainage ditches, which are constructed to drain the land in preparation for peat extraction, also contribute to
 8 the flux of CH₄ through *in situ* production and lateral transfer of CH₄ from the organic soil matrix (IPCC 2013).

9 Off-site CO₂ emissions from managed peatlands occur from waterborne carbon losses and the horticultural and
 10 landscaping use of peat. Dissolved organic carbon from water drained off peatlands reacts within aquatic ecosystems
 11 and is converted to CO₂, then emitted to the atmosphere (Billet et al. 2004 as cited in IPCC 2013). During the
 12 horticultural and landscaping use of peat, nutrient-poor (but fertilizer-enriched) peat tends to be used in bedding
 13 plants and in greenhouse and plant nursery production, whereas nutrient-rich (but relatively coarse) peat is used
 14 directly in landscaping, athletic fields, golf courses, and plant nurseries. Most (nearly 94 percent) of the CO₂
 15 emissions from peat occur off-site, as the peat is processed and sold to firms which, in the United States, use it
 16 predominantly for the aforementioned horticultural and landscaping purposes.

17 Total emissions from *Peatlands Remaining Peatlands* were estimated to be 0.8 MMT CO₂ Eq. in 2015 (see Table
 18 6-44) comprising 0.8 MMT CO₂ Eq. (763 kt) of CO₂, 0.001 MMT CO₂ Eq. (0.002 kt) of N₂O, and 0.004 MMT CO₂
 19 Eq. (0.16 kt) of CH₄. Total emissions in 2015 were about 2 percent less than total emissions in 2014. Peat
 20 production in Alaska in 2015 was not reported in *Alaska's Mineral Industry 2014* report. However, peat production
 21 reported in the lower 48 states in 2015 was two percent less than in 2014, resulting in a decrease in total emissions
 22 for the 48 states and Alaska from *Peatlands Remaining Peatlands* in 2015 compared to 2014.

23 Total emissions from *Peatlands Remaining Peatlands* have fluctuated between 0.8 and 1.3 MMT CO₂ Eq. across the
 24 time series with a decreasing trend from 1990 until 1993, followed by an increasing trend until reaching peak
 25 emissions in 2000. After 2000, emissions generally decreased until 2006 and then increased until 2009. The trend
 26 reversed in 2009 and total emissions have generally decreased between 2009 and 2015. Carbon dioxide emissions
 27 from *Peatlands Remaining Peatlands* have fluctuated between 0.8 and 1.3 MMT CO₂ across the time series, and
 28 these emissions drive the trends in total emissions. Methane and N₂O emissions remained close to zero across the
 29 time series. Nitrous oxide emissions showed a decreasing trend from 1990 until 1995, followed by an increasing
 30 trend through 2001. Nitrous oxide emissions decreased between 2001 and 2006, followed by a leveling off between
 31 2008 and 2010, and a general decline between 2011 and 2015. Methane emissions decreased from 1990 until 1995,
 32 followed by an increasing trend through 2000, a period of fluctuation through 2010, and a general decline between
 33 2010 and 2015.

34 **Table 6-44: Emissions from *Peatlands Remaining Peatlands* (MMT CO₂ Eq.)**

Gas	1990	2005	2011	2012	2013	2014	2015
CO ₂	1.1	1.1	0.9	0.8	0.8	0.8	0.8
Off-site	1.0	1.0	0.9	0.8	0.7	0.7	0.7
On-site	0.1	0.1	0.1	0.1	+	0.1	+
N ₂ O (On-site)	+	+	+	+	+	+	+
CH ₄ (On-site)	+	+	+	+	+	+	+
Total	1.1	1.1	0.9	0.8	0.8	0.8	0.8

+ Does not exceed 0.05 MMT CO₂ Eq.

Note: These numbers are based on U.S. production data in accordance with Tier 1 guidelines, which does not take into account imports, exports, and stockpiles (i.e., apparent consumption). Off-site N₂O emissions are not estimated to avoid double-counting N₂O emitted from the fertilizer that the peat is mixed with prior to horticultural use (see IPCC 2006). Totals may not sum due to independent rounding.

35 **Table 6-45: Emissions from *Peatlands Remaining Peatlands* (kt)**

Gas	1990	2005	2011	2012	2013	2014	2015
CO ₂	1,055	1,101	926	812	770	775	763
Off-site	985	1,030	866	760	720	725	713

On-site	70	71	60	53	50	50	49
N ₂ O (On-site)	+	+	+	+	+	+	+
CH ₄ (On-site)	+	+	+	+	+	+	+

+ Does not exceed 0.5 kt

Note: These numbers are based on U.S. production data in accordance with Tier 1 guidelines, which does not take into account imports, exports, and stockpiles (i.e., apparent consumption). Off-site N₂O emissions are not estimated to avoid double-counting N₂O emitted from the fertilizer that the peat is mixed with prior to horticultural use (see IPCC 2006). Totals may not sum due to independent rounding.

1 Methodology

2 Off-Site CO₂ Emissions

3 Carbon dioxide emissions from domestic peat production were estimated using a Tier 1 methodology consistent with
4 IPCC (2006). Off-site CO₂ emissions from *Peatlands Remaining Peatlands* were calculated by apportioning the
5 annual weight of peat produced in the United States (Table 6-46) into peat extracted from nutrient-rich deposits and
6 peat extracted from nutrient-poor deposits using annual percentage-by-weight figures. These nutrient-rich and
7 nutrient-poor production values were then multiplied by the appropriate default C fraction conversion factor taken
8 from IPCC (2006) in order to obtain off-site emission estimates. For the lower 48 states, both annual percentages of
9 peat type by weight and domestic peat production data were sourced from estimates and industry statistics provided
10 in the *Minerals Yearbook* and *Mineral Commodity Summaries* from the U.S. Geological Survey (USGS 1995
11 through 2015; USGS 2016). To develop these data, the U.S. Geological Survey (USGS; U.S. Bureau of Mines prior
12 to 1997) obtained production and use information by surveying domestic peat producers. On average, about 75
13 percent of the peat operations respond to the survey; and USGS estimates data for non-respondents on the basis of
14 prior-year production levels (Apodaca 2011).

15 The Alaska estimates rely on reported peat production from the annual *Alaska's Mineral Industry* reports (DGGS
16 1993 through 2015). Similar to the U.S. Geological Survey, the Alaska Department of Natural Resources, Division
17 of Geological & Geophysical Surveys (DGGS) solicits voluntary reporting of peat production from producers for the
18 *Alaska's Mineral Industry* report. However, the report does not estimate production for the non-reporting producers,
19 resulting in larger inter-annual variation in reported peat production from Alaska depending on the number of
20 producers who report in a given year (Szumigala 2011). In addition, in both the lower 48 states and Alaska, large
21 variations in peat production can also result from variations in precipitation and the subsequent changes in moisture
22 conditions, since unusually wet years can hamper peat production. The methodology estimates Alaska emissions
23 separately from lower 48 emissions because the state conducts its own mineral survey and reports peat production
24 by volume, rather than by weight (Table 6-47). However, volume production data were used to calculate off-site
25 CO₂ emissions from Alaska applying the same methodology but with volume-specific C fraction conversion factors
26 from IPCC (2006).⁶³ Peat production was not reported for 2015 in *Alaska's Mineral Industry 2014* report (DGGS
27 2015); and reliable data are not available beyond 2012, so Alaska's peat production in 2013, 2014, and 2015
28 (reported in cubic yards) was assumed to be equal to the 2012 value.

29 Consistent with IPCC (2013) guidelines, off-site CO₂ emissions from dissolved organic carbon were estimated based
30 on the total area of peatlands managed for peat extraction, which is calculated from production data using the
31 methodology described in the *On-Site CO₂ Emissions* section below. CO₂ emissions from dissolved organic C were
32 estimated by multiplying the area of peatlands by the default emissions factor for dissolved organic C provided in
33 IPCC (2013).

34 The *apparent consumption* of peat, which includes production plus imports minus exports plus the decrease in
35 stockpiles, in the United States is over times the amount of domestic peat production. However, consistent with the
36 Tier 1 method whereby only domestic peat production is accounted for when estimating off-site emissions, off-site
37 CO₂ emissions from the use of peat not produced within the United States are not included in the Inventory. The
38 United States has largely imported peat from Canada for horticultural purposes; from 2011 to 2014, imports of
39 sphagnum moss (nutrient-poor) peat from Canada represented 97 percent of total U.S. peat imports (USGS 2016).

⁶³ Peat produced from Alaska was assumed to be nutrient poor; as is the case in Canada, "where deposits of high-quality [but nutrient poor] sphagnum moss are extensive" (USGS 2008).

1 Most peat produced in the United States is reed-sedge peat, generally from southern states, which is classified as
 2 nutrient rich by IPCC (2006). Higher-tier calculations of CO₂ emissions from apparent consumption would involve
 3 consideration of the percentages of peat types stockpiled (nutrient rich versus nutrient poor) as well as the
 4 percentages of peat types imported and exported.

5 **Table 6-46: Peat Production of Lower 48 States (kt)**

Type of Deposit	1990	2005	2011	2012	2013	2014	2015
Nutrient-Rich	595.1	657.6	511.2	409.9	418.5	416.5	409.4
Nutrient-Poor	55.4	27.4	56.8	78.1	46.5	51.5	50.6
Total Production	692.0	685.0	568.0	488.0	465.0	468.0	460.0

7 *On-site CO₂ Emissions*

8 IPCC (2006) suggests basing the calculation of on-site emission estimates on the area of peatlands managed for peat
 9 extraction differentiated by the nutrient type of the deposit (rich versus poor). Information on the area of land
 10 managed for peat extraction is currently not available for the United States, but in accordance with IPCC (2006), an
 11 average production rate for the industry was applied to derive an area estimate. In a mature industrialized peat
 12 industry, such as exists in the United States and Canada, the vacuum method can extract up to 100 metric tons per
 13 hectare per year (Cleary et al. 2005 as cited in IPCC 2006).⁶⁴ The area of land managed for peat extraction in the
 14 lower 48 states of the United States was estimated using nutrient-rich and nutrient-poor production data and the
 15 assumption that 100 metric tons of peat are extracted from a single hectare in a single year. The annual land area
 16 estimates were then multiplied by the IPCC (2013) default emission factor in order to calculate on-site CO₂ emission
 17 estimates. Production data are not available by weight for Alaska. In order to calculate on-site emissions resulting
 18 from *Peatlands Remaining Peatlands* in Alaska, the production data by volume were converted to weight using
 19 annual average bulk peat density values, and then converted to land area estimates using the same assumption that a
 20 single hectare yields 100 metric tons. The IPCC (2006) on-site emissions equation also includes a term which
 21 accounts for emissions resulting from the change in C stocks that occurs during the clearing of vegetation prior to
 22 peat extraction. Area data on land undergoing conversion to peatlands for peat extraction is also unavailable for the
 23 United States. However, USGS records show that the number of active operations in the United States has been
 24 declining since 1990; therefore, it seems reasonable to assume that no new areas are being cleared of vegetation for
 25 managed peat extraction. Other changes in C stocks in living biomass on managed peatlands are also assumed to be
 26 zero under the Tier 1 methodology (IPCC 2006 and 2013).

27 *On-site N₂O Emissions*

28 IPCC (2006) suggests basing the calculation of on-site N₂O emission estimates on the area of nutrient-rich peatlands
 29 managed for peat extraction. These area data are not available directly for the United States, but the on-site CO₂
 30 emissions methodology above details the calculation of area data from production data. In order to estimate N₂O
 31 emissions, the area of nutrient rich *Peatlands Remaining Peatlands* was multiplied by the appropriate default
 32 emission factor taken from IPCC (2013).

⁶⁴ The vacuum method is one type of extraction that annually “mills” or breaks up the surface of the peat into particles, which then dry during the summer months. The air-dried peat particles are then collected by vacuum harvesters and transported from the area to stockpiles (IPCC 2006).

1 *On-site CH₄ Emissions*

2 IPCC (2013) also suggests basing the calculation of on-site CH₄ emission estimates on the total area of peatlands
 3 managed for peat extraction. Area data is derived using the calculation from production data described in the *On-site*
 4 *CO₂ Emissions* section above. In order to estimate CH₄ emissions from drained land surface, the area of *Peatlands*
 5 *Remaining Peatlands* was multiplied by the emission factor for direct CH₄ emissions taken from IPCC (2013). In
 6 order to estimate CH₄ emissions from drainage ditches, the total area of peatland was multiplied by the default
 7 fraction of peatland area that contains drainage ditches, and the appropriate emission factor taken from IPCC (2013).

8 **Uncertainty and Time-Series Consistency**

9 A Monte Carlo (Approach 2) uncertainty analysis was applied to estimate the uncertainty of CO₂, CH₄, and N₂O
 10 emissions from *Peatlands Remaining Peatlands*, using the following assumptions:

- 11 • The uncertainty associated with peat production data was estimated to be ± 25 percent (Apodaca 2008) and
 12 assumed to be normally distributed.
- 13 • The uncertainty associated with peat production data stems from the fact that the USGS receives data from
 14 the smaller peat producers but estimates production from some larger peat distributors. The peat type
 15 production percentages were assumed to have the same uncertainty values and distribution as the peat
 16 production data (i.e., ± 25 percent with a normal distribution).
- 17 • The uncertainty associated with the reported production data for Alaska was assumed to be the same as for
 18 the lower 48 states, or ± 25 percent with a normal distribution. It should be noted that the DGGS estimates
 19 that around half of producers do not respond to their survey with peat production data; therefore, the
 20 production numbers reported are likely to underestimate Alaska peat production (Szumigala 2008).
- 21 • The uncertainty associated with the average bulk density values was estimated to be ± 25 percent with a
 22 normal distribution (Apodaca 2008).
- 23 • IPCC (2006 and 2013) gives uncertainty values for the emissions factors for the area of peat deposits
 24 managed for peat extraction based on the range of underlying data used to determine the emission factors.
 25 The uncertainty associated with the emission factors was assumed to be triangularly distributed.
- 26 • The uncertainty values surrounding the C fractions were based on IPCC (2006) and the uncertainty was
 27 assumed to be uniformly distributed.
- 28 • The uncertainty values associated with the fraction of peatland covered by ditches was assumed to be ± 100
 29 percent with a normal distribution based on the assumption that greater than 10 percent coverage, the upper
 30 uncertainty bound, is not typical of drained organic soils outside of The Netherlands (IPCC 2013).

31 The results of the Approach 2 quantitative uncertainty analysis are summarized in Table 6-48. CO₂ emissions from
 32 *Peatlands Remaining Peatlands* in 2015 were estimated to be between 0.6 and 0.9 MMT CO₂ Eq. at the 95 percent
 33 confidence level. This indicates a range of 16 percent below to 16 percent above the 2015 emission estimate of 0.8
 34 MMT CO₂ Eq. Methane emissions from *Peatlands Remaining Peatlands* in 2015 were estimated to be between
 35 0.002 and 0.007 MMT CO₂ Eq. This indicates a range of 58 percent below to 78 percent above the 2015 emission
 36 estimate of 0.004 MMT CO₂ Eq. Nitrous oxide emissions from *Peatlands Remaining Peatlands* in 2015 were
 37 estimated to be between 0.0003 and 0.0009 MMT CO₂ Eq. at the 95 percent confidence level. This indicates a range
 38 of 53 percent below to 53 percent above the 2015 emission estimate of 0.0006 MMT CO₂ Eq.

39 **Table 6-48: Approach 2 Quantitative Uncertainty Estimates for CO₂, CH₄, and N₂O Emissions**
 40 **from *Peatlands Remaining Peatlands* (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Peatlands Remaining Peatlands	CO ₂	0.8	0.6	0.9	-16%	16%
Peatlands Remaining Peatlands	CH ₄	+	+	+	-58%	78%
Peatlands Remaining Peatlands	N ₂ O	+	+	+	-53%	53%

+ Does not exceed 0.05 MMT CO₂ Eq.

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

1 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
2 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
3 above.

4 **QA/QC and Verification**

5 A QA/QC analysis was performed to review input data and calculations, and no issues were identified. In addition,
6 the emission trends were analyzed to ensure they reflected activity data trends.

7 **Recalculations Discussion**

8 The emissions estimates for *Peatlands Remaining Peatlands* were updated for 2015 using the Peat section of the
9 *Mineral Commodity Summaries 2016*. The new edition provided 2015 data and updated 2014 data for the lower 48
10 states. Although Alaska peat production data for 2015 was unavailable, 2014 data was recently published in the
11 *Alaska's Mineral Industry 2014* report. However, the reported values represented an apparent 98 percent decrease in
12 production since 2012. Due to the uncertainty of the most recent data, 2013, 2014, and 2015 values were assumed to
13 be equal to the 2012 value. If updated data are available for the next inventory cycle, this will result in a
14 recalculation in the next Inventory report.

15 **Planned Improvements**

16 In order to further improve estimates of CO₂, N₂O, and CH₄ emissions from *Peatlands Remaining Peatlands*, future
17 efforts will investigate if data sources exist for determining the quantity of peat harvested per hectare and the total
18 area undergoing peat extraction.

19 Efforts will also be made to find a new source for Alaska peat production. The current source has not been reliably
20 updated since 2012 and future publication of these data may discontinue.

21 The *2013 Supplement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories: Wetlands* describes
22 inventory methodologies for various wetland source categories. In the 1990–2013 Inventory, EPA began including
23 updated methods for *Peatlands Remaining Peatlands* to align them with the *2013 IPCC Supplement*. For future
24 inventories, EPA will determine if additional updates are needed to further address the *2013 IPCC Supplement* for
25 *Peatlands Remaining Peatlands*.

26 The *2006 IPCC Guidelines* do not cover all wetland types; they are restricted to peatlands drained and managed for
27 peat extraction, conversion to flooded lands, and some guidance for drained organic soils. They also do not cover all
28 of the significant activities occurring on wetlands (e.g., rewetting of peatlands). Since this inventory only includes
29 *Peatlands Remaining Peatlands*, additional wetland types and activities found in the *2013 IPCC Supplement* will be
30 reviewed to determine if they apply to the United States. For those that do, available data will be investigated to
31 allow for the estimation of greenhouse gas fluxes in future inventory years.

32 **Coastal Wetlands Remaining Coastal Wetlands**

33 The Inventory recognizes Wetlands as a “land-use that includes land covered or saturated for all or part of the year,
34 in addition to areas of lakes, reservoirs and rivers.” Consistent with ecological definitions of wetlands,⁶⁵ the United
35 States has historically included under the category of Wetlands those coastal shallow water areas of estuaries and
36 bays that fall in the Land Representation.

37 Additional guidance on quantifying greenhouse gas emissions and removals on Coastal Wetlands is provided in the
38 *2013 Supplement to the 2006 IPCC Guidelines for National GHG Inventories: Wetlands (Wetlands Supplement)*,
39 which recognizes the particular importance of vascular plants in sequestering CO₂ from the atmosphere and building
40 soil carbon stocks. Thus, the *Wetlands Supplement* provides specific guidance on quantifying emissions on organic

⁶⁵ See <<https://water.usgs.gov/nwsum/WSP2425/definitions.html>>

1 and mineral soils that are covered or saturated for part of the year by tidal freshwater, brackish or saline water and
2 are vegetated by vascular plants and may extend seaward to the maximum depth of vascular plant vegetation.

3 The United States recognizes both Vegetated Wetlands and Unvegetated Open Water as Coastal Wetlands. Per
4 guidance provided by the *Wetlands Supplement* sequestration of carbon into biomass and soils carbon pools is
5 recognized only in Vegetated Coastal Wetlands and not to occur in Unvegetated Open Water Coastal Wetlands. The
6 United States takes the additional step of recognizing that stock losses occur when Vegetated Coastal Wetlands are
7 converted to Unvegetated Coastal Wetlands.

8 This Inventory includes all privately-owned and federal coastal wetlands along the oceanic shores on the
9 conterminous U.S., but does not include *Coastal Wetlands Remaining Coastal Wetlands* in Alaska or Hawaii.
10 Seagrasses are not currently included within the Inventory due to insufficient data on distribution, change through
11 time and carbon (C) stocks or C stock changes as a result of anthropogenic influence.

12 Under the *Coastal Wetlands Remaining Coastal Wetlands* category, the following emissions and removals are
13 quantified in this chapter.

- 14 1) C stock changes and CH₄ emissions on *Vegetated Coastal Wetlands Remaining Vegetated Coastal*
15 *Wetlands*.
- 16 2) C changes with conversion of Vegetated Coastal Wetlands to Unvegetated Open Water Coastal Wetlands.
- 17 3) C stock changes with conversion of Unvegetated Open Water Coastal Wetlands to Vegetated Coastal
18 Wetlands.
- 19 4) N₂O emissions from aquaculture.

20 Vegetated coastal wetlands hold C in all five C pools (i.e., aboveground, belowground, dead organic matter [DOM;
21 dead wood and litter], and soil) though typically soil C and, to a lesser extent aboveground- and belowground-
22 biomass, are the dominant pools, depending on wetland type (i.e., forested vs. marsh). Vegetated Coastal Wetlands
23 are net accumulators of soil C as soils C accumulates under anaerobic soil conditions. Emissions from soil C and
24 biomass stocks occur when Vegetated Coastal Wetlands are converted to Unvegetated Open Water Coastal
25 Wetlands (i.e., when managed Vegetated Coastal Wetlands are lost due to subsidence), but are still recognized as
26 Coastal Wetlands in this Inventory. These C emissions resulting from conversion to Unvegetated Open Water
27 Coastal Wetlands, can cause the release of many years of accumulated soil C. Conversion of Unvegetated Open
28 Water Coastal Wetlands to Vegetated Coastal Wetlands initiates the re-building of soil C stocks within soils and
29 biomass. In application of *2013 IPCC Wetlands Supplement* methodologies for CH₄ emissions, coastal wetlands in
30 salinity conditions less than half that of sea water are sources of CH₄ and are a result of slow decomposition of
31 organic matter under freshwater, anaerobic conditions. Conversion of Vegetated Coastal Wetlands to or from
32 Unvegetated Open Water Coastal Wetlands do not result in a change in salinity condition and are assumed to have
33 no impact on CH₄ emissions. *2013 IPCC Wetlands Supplement* guidance provides methodologies to estimate nitrous
34 oxide emissions on coastal wetlands occur due Aquaculture. While N₂O emissions can occur due to anthropogenic N
35 loading from the watershed and atmospheric deposition, these emissions are not reported. The N₂O emissions from
36 Aquaculture result from the N derived from consumption of the applied food stock which is then excreted as N load
37 available for conversion to N₂O.

38 The *Wetlands Supplement* provides procedures for estimating CO₂ emissions and removals and CH₄ emissions from
39 mangroves, tidal marshes and seagrasses. Depending upon their height and area, emissions and removals from
40 managed mangroves may be reported under the Forest Land category or under Coastal Wetlands. All non-drained,
41 intact coastal marshes are intended to be reported under Coastal Wetlands

42 Because of human use and level of regulatory oversight, all coastal wetlands within the conterminous U.S. are
43 within the managed land area described in Section 6.1, and as such all estimates of CO₂ emissions and removals, and
44 emissions of CH₄, and N₂O from aquaculture are included in this Inventory. At the present stage of Inventory
45 development, Coastal Wetlands are not explicitly shown in the Land Representation analysis while work continues
46 harmonizing data from NOAA's Coastal Change Analysis Program⁶⁶ with NRI data used to compile the Land
47 Representation. However, a check was undertaken to confirm that Coastal Wetlands recognized by C-CAP
48 represented a subset of Wetlands recognized by the NRI for marine coastal states.

⁶⁶ See <<https://coast.noaa.gov/digitalcoast/tools/lca>>

Emissions and Removals from Vegetated Coastal Wetlands

Remaining Vegetated Coastal Wetlands

The conterminous U.S. hosts 2.9 million hectares of intertidal *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands* comprised of tidally influenced palustrine emergent marsh (599,005 ha), palustrine scrub shrub (137,590 ha) and estuarine emergent marsh (1,853,863 ha), estuarine scrub shrub (96,998 ha) and estuarine forest (191,473 ha). Mangroves fall under both estuarine forest and estuarine scrub shrub categories depending upon height. Dwarf mangroves, found in Texas, do not attain the height status to be recognized as Forest Land, and are therefore always classified within *Vegetated Coastal Wetlands*. *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands* are found in cold temperate (52,403 ha), warm temperate (890,458 ha), subtropical (1,879,314 ha) and Mediterranean (56,755 ha) climate zones.

Soils are the largest pool of C in *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands* reflecting long-term removal of atmospheric CO₂ by vegetation and transfer into the soil pool in the form of decaying organic matter. Emissions of soil C are not assumed to occur in coastal wetlands that remain vegetated. In this Inventory, only C stock changes within soils are reported as insufficient data exists on C stock changes in biomass, DOM and litter. Methane emissions from decomposition of organic matter in anaerobic conditions are significant at salinity less than half that of sea water. Mineral and organic soils are not differentiated in terms of C removals or CH₄ emissions.

Table 6-49 through Table 6-52 below summarize nationally aggregated soil C stock emissions and removals and CH₄ emissions on *Vegetated Coastal Wetlands*. Intact *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands* hold a large stock of C (here estimated to be 870 MMT C (3,190 MMT CO₂ Eq.) within the top 1 meter of soil to which C is accumulated each year at a rate of 12.2 MMT CO₂ Eq. Methane emissions of 3.5 of MMT CO₂ Eq. offset C removals resulting in an annual net C removal rate of 8.7 MMT CO₂ Eq. Due to federal regulatory protection, loss of *Vegetated Coastal Wetland* area slowed considerably in the 1970s and currently rates of C stock change and CH₄ emissions are relatively constant over time. Losses of *Vegetated Coastal Wetlands* to *Unvegetated Open Water Coastal Wetlands* (described later in this chapter) and to other land uses do occur, which because of the depth to which soil C stocks are impacted, do have a significant impact on the net emissions and removals on *Coastal Wetlands*.

Table 6-49: Net CO₂ Flux from Soil C Stock Changes in *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands* (MMT CO₂ Eq.)

Year	1990	2005	2011	2012	2013	2014	2015
Net Flux	(12.1)	(12.2)	(12.2)	(12.2)	(12.2)	(12.2)	(12.2)

Note: Parentheses indicate net sequestration.

Estimates prior to 1996 and after 2010 are extrapolated from the trend based on Coastal Change Analysis Program (C-CAP) data and therefore may not fully reflect changes occurring in the latter part of the time series. Mineral and organic soils are not differentiated in terms of C removals. Quality control measures are still underway and estimates will be finalized after public review.

Table 6-50: Net CO₂ Flux from Soil C Stock Changes in *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands* (MMT C)

Year	1990	2005	2011	2012	2013	2014	2015
Net Flux	(3.3)	(3.3)	(3.3)	(3.3)	(3.3)	(3.3)	(3.3)

 4 ***Wetlands* (kt CH₄)**

Year	1990	2005	2011	2012	2013	2014	2015
Net Flux	138	140	141	141	141	141	141

Note: Parentheses indicate net sequestration.

Estimates prior to 1996 and after 2010 are extrapolated based on C-CAP data and therefore may not fully reflect changes occurring in the latter part of the time series. Mineral and organic soils are not differentiated in terms of methane emissions. Quality control measures are still underway and estimates will be finalized after public review.

5 Methodology

6 The following section includes a brief description of the methodology used to estimate changes in soil C stocks and
 7 emissions of CH₄ for *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands*.

8 *Soil Carbon Stock Changes*

9 Soil C removals are estimated for *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands* for both
 10 mineral and organic soils on wetlands below the elevation of high tides (taken to be mean high water spring tide
 11 elevation) and as far seawards as the extent of intertidal vascular plants within the U.S. Land Representation
 12 according to the national LiDAR dataset, the national network of tide gauges and land use histories recorded in the
 13 1996, 2001, 2005 and 2010 NOAA C-CAP surveys.⁶⁷ Federal and non-federal lands are represented. Trends in land
 14 cover change are extrapolated to 1990 and 2015 from these datasets. Based upon NOAA C-CAP, coastal wetlands
 15 are subdivided into freshwater (Palustrine) and saline (Estuarine) classes and further subdivided into emergent
 16 marsh, scrub shrub and forest classes.⁶⁸ Soil C stock changes, stratified by climate zones and wetland classes, are
 17 derived from a synthesis of peer-reviewed literature (Mangrove pool and removals data: *Cahoon & Lynch*
 18 *unpublished data*; *Lynch 1989*; *Callaway et al. 1997*; *Chen & Twilley 1999*; *McKee & Faulkner 2000*; *Ross et al.*
 19 *2000*; *Chmura et al. 2003*; *Perry & Mendelsohn 2009*; *Castaneda-Moya et al. 2013*; *Henry & Twilley 2013*;
 20 *Doughty et al. 2015*; *Marchio et al. 2016*. Tidal marsh pool and removals data: *Anisfeld unpublished data*; *Cahoon*
 21 *unpublished data*; *Cahoon & Lynch unpublished data*; *Chmura unpublished data*; *McCaffrey & Thomson 1980*;
 22 *Hatton 1981*; *Callaway et al. 1987*; *Craft et al. 1988*; *Cahoon & Turner 1989*; *Patrick & DeLaune 1990*; *Kearney*
 23 *& Stevenson 1991*; *Cahoon et al. 1996*; *Callaway et al. 1997*; *Roman et al. 1997*; *Bryant & Chabrek 1998*; *Orson et*
 24 *al. 1998*; *Markewich et al. 1998*; *Anisfeld et al. 1999*; *Connor et al. 2001*; *Choi & Wang 2001*; *Chmura et al. 2003*;
 25 *Hussein et al. 2004*; *Craft 2007*; *Miller et al. 2008*; *Drexler et al. 2009*; *Perry & Mendelsohn 2009*; *Loomis &*
 26 *Craft 2010*; *EPA's NWCA 2011*; *Callaway et al. 2012*; *Henry & Twilley 2013*; *Weston et al. 2014*). To estimate soil
 27 C stock changes no differentiation is made between organic and mineral soils.

28 Tier 2 level estimates of soil C removal associated with annual soil C accumulation from managed *Vegetated*
 29 *Coastal Wetlands Remaining Vegetated Coastal Wetlands* were developed with country-specific soil C removal
 30 factors multiplied by activity data of land area for *Vegetated Coastal Wetlands Remaining Vegetated Coastal*

⁶⁷ See <<https://coast.noaa.gov/digitalcoast/tools/lca.html>>

⁶⁸ See <<https://coast.noaa.gov/digitalcoast/tools/lca.html>>

1 *Wetlands*. The methodology follows Eq. 4.7, Chapter 4 of the *Wetlands Supplement*, and is applied to the area of
 2 *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands* on an annual basis. Emission factors were
 3 developed from literature references that provided soil C removal factors disaggregated by climate region,
 4 vegetation type by salinity range (estuarine or palustrine) as identified using NOAA C-CAP as described above.
 5 Quantification of regional coastal wetland above and belowground biomass C stock changes for woody and
 6 perennial herbaceous vegetation, DOM [dead wood and litter] C stocks are in development and are not presented
 7 this year, though will be included in future reports.

8 *Soil Methane Emissions*

9 Tier 1 estimates of CH₄ emissions for *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands* are
 10 derived from the same wetland map used to in the analysis of wetland soil C fluxes, produced from C-CAP, LiDAR
 11 and tidal data, in combination with default CH₄ emission factors provided in Table 4.14 of the *Wetlands Supplement*.
 12 The methodology follows Eq. 4.9, Chapter 4 of the *Wetlands Supplement*, and applied to the area of *Vegetated*
 13 *Coastal Wetlands Remaining Vegetated Coastal Wetlands* on an annual basis. The AR4 global warming potential
 14 factor of 25 was used in converting CH₄ to CO₂ Eq. values.

15 **Uncertainty and Time-Series Consistency**

16 Underlying uncertainties in estimates of soil C stock changes and CH₄ include error in uncertainties associated with
 17 Tier 2 literature values of soil C stocks and CH₄ flux, assumptions that underlie the methodological approaches
 18 applied and uncertainties linked to interpretation of remote sensing data. Uncertainty specific to *Vegetated Coastal*
 19 *Wetlands Remaining Vegetated Coastal Wetlands* include differentiation of palustrine and estuarine community
 20 classes, which determines the soil C stock and CH₄ flux applied. Soil C stocks and CH₄ fluxes applied are
 21 determined from vegetation community classes across the coastal zone and identified by NOAA C-CAP.
 22 Community classes are further subcategorized by climate zones and growth form (forest, shrub-scrub, marsh).
 23 Uncertainties for soil C stock data for all subcategories are not available and thus assumptions were applied using
 24 expert judgement about the most appropriate assignment of a soil C stock to a disaggregation of a community class.
 25 Because mean soil C stocks for each available community class are in a fairly narrow range, the same overall
 26 uncertainty was assigned to each (i.e., applying approach for asymmetrical errors, where the largest uncertainty for
 27 any one soil C stock referenced using published literature values for a community class; uncertainty approaches
 28 provide that if multiple values are available for a single parameter, the highest uncertainty value should be applied to
 29 the propagation of errors; IPCC 2000). Uncertainties for CH₄ flux are the Tier 1 default values reported in the
 30 *Wetlands Supplement*. Overall uncertainty of the NOAA C-CAP remote sensing product is 15 percent. This is in the
 31 range of remote sensing methods (±10-15 percent; IPCC 2003). However, there is significant uncertainty in salinity
 32 ranges for tidal and non-tidal estuarine wetlands and activity data used to apply CH₄ flux emission factors
 33 (delineation of an 18 ppt boundary) will need significant improvement to reduce uncertainties.

34 **Table 6-53: Approach 1 Quantitative Uncertainty Estimates for C Stock Changes occurring**
 35 **within *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands* (MMT CO₂ Eq.**
 36 **and Percent)**

Source	2015 Flux Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Flux Estimate (MMT CO ₂ Eq.) (%)			
		Lower Bound	Upper Bound	Lower Bound	Upper Bound
Combined Uncertainty for Flux Associated with Wetlands Soil C Stock Change in <i>Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands</i>	(12.2)	(15.8)	(8.6)	-29.5%	29.5%

Notes: Parentheses indicate net sequestration. Quality control measures are still underway and estimates will be finalized after public review.

Table 6-54: Approach 1 Quantitative Uncertainty Estimates for CH₄ Emissions occurring within *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands* (MMT CO₂ Eq. and Percent)

Source	2015 Flux Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Flux Estimate (MMT CO ₂ Eq.)			
		Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Combined Uncertainty for Flux Associated with CH ₄ emissions in <i>Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands</i>	3.5	2.5	4.5	-29.8%	29.8%

Note: Quality control measures are still underway and estimates will be finalized after public review.

Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

QA/QC and Verification

NOAA provided National LiDAR Dataset, tide data, and C-CAP land cover and land cover change mapping, all of which are subject to agency internal QA/QC assessment. Acceptance of final datasets into archive and dissemination are contingent upon the product compilation are compliant with mandatory QA/QC requirements (McCombs, et al., 2016). QA/QC and verification of soil C stock dataset has been provided by the Smithsonian Environmental Research Center and Coastal Wetland Inventory team leads who reviewed summary tables against reviewed sources. Land cover estimates were assessed to ensure that the total land area did not change over the time series in which the inventory was developed, and verified by a second QA team. A team of two evaluated and verified there were no computational errors within the calculation worksheets. Soil C stock, emissions/removals data were based upon peer-reviewed literature and CH₄ emission factors derived from the IPCC Wetlands Supplement.

Planned Improvements

A USGS/ NASA Carbon Monitoring System investigation is in progress to establish a U.S. country-specific database of soil C stock, wetland biomass and CH₄ emissions. Refined error analysis combining land cover change and C stock estimates will be provided. Through this work a model is in development to represent changes in soil C stocks. This research effort is due to be complete November 2017, with the potential to include the results from the new model in the 1990 to 2016 Inventory (2018 submission) or the 1990 to 2017 Inventory (2019 submission).

Emissions from Vegetated Coastal Wetlands Converted to Unvegetated Open Water Coastal Wetlands

Conversion of intact Vegetated Coastal Wetlands to Unvegetated Open Water Coastal Wetlands is a source of emissions from both soil and biomass C stocks. It is estimated that 8,428 ha of Vegetated Coastal Wetlands were converted to Unvegetated Open Water Coastal Wetlands in 2015. The Mississippi Delta represents more than 40 percent of the total coastal wetland of the U.S, and over 90 percent of the conversion of Vegetated Coastal Wetlands to Unvegetated Open Water Coastal Wetlands. The drivers of coastal wetlands loss include legacy human impacts on sediment supply through rerouting river flow, direct impacts of channel cutting on hydrology, salinity and sediment delivery and accelerated subsidence from aquafer extraction. Each of these drivers directly contributes to wetland erosion and subsidence, while also reducing the resilience of the wetland to build with sea level rise or recover from hurricane disturbance. Over recent decades the rate of Mississippi Delta wetland loss has slowed, though episodic mobilization of sediment occurs during hurricane events (Couvillion et al., 2011; Couvillion et al., 2016). The most recent land cover analysis recorded by the C-CAP surveys 2005-2010 coincides with two such events, hurricanes Katrina and Rita both in 2005.

1 Shallow nearshore open water within the U.S. Land Representation is recognized as falling under the Wetlands
 2 category within the U.S. Inventory. Changes in biomass are not presented this year but will be in the future (see
 3 Planned Improvements). While high resolution mapping of coastal wetlands provides data to support Tier 2
 4 approaches for tracking land cover change, the depth to which sediment is lost is less clear. This Inventory adopts
 5 the Tier 1 methodological guidance from the *Wetlands Supplement* for estimating emissions following the
 6 methodology for excavation (see Methodology section, below) when Vegetated Coastal Wetlands are converted to
 7 Unvegetated Open Water Coastal Wetlands, assuming a 1 m depth of disturbed soil. This 1 m depth of disturbance is
 8 consistent with estimates of wetland C loss provided in the literature (Crooks, et al., 2009; Couvillon et al., 2011;
 9 Delaune and White, 2012; IPCC 2013). A Tier 1 assumption is also adopted that all mobilized C is immediately
 10 returned to the atmosphere (as assumed for terrestrial land use categories), rather than redeposited in long-term C
 11 storage. The science is currently under evaluation to adopt more refined emissions factors for mobilized coastal
 12 wetland C based upon the geomorphic setting of the depositional environment.

13 **Table 6-55: Net CO₂ Flux from Soil C Stock Changes in *Vegetated Coastal Wetlands***
 14 ***Converted to Unvegetated Open Water Coastal Wetlands (MMT CO₂ Eq.)***

Year	1990	2005	2011	2012	2013	2014	2015
Net Soil Flux	3.5	2.1	3.5	3.5	3.5	3.5	3.5

Note: Estimates prior to 1996 and after 2010 are extrapolated based on C-CAP data and therefore may not fully reflect changes occurring in the latter part of the time series. Mineral and Organic Soils are not differentiated in terms of C removals. Quality control measures are still underway and estimates will be finalized after public review.

15 **Table 6-56: Net CO₂ Flux from Soil C Stock Changes in *Vegetated Coastal Wetlands***
 16 ***Converted to Unvegetated Open Water Coastal Wetlands (MMT C)***

Year	1990	2005	2011	2012	2013	2014	2015
Net Soil Flux	1.0	0.6	1.0	1.0	1.0	1.0	1.0

Note: Estimates prior to 1996 and after 2010 are extrapolated based on C-CAP data and therefore may not fully reflect changes occurring in the latter part of the time series. Mineral and Organic Soils are not differentiated in terms of C removals. Quality control measures are still underway and estimates will be finalized after public review.

17 Methodology

18 The following section includes a brief description of the methodology used to estimate changes in soil C stocks for
 19 *Vegetated Coastal Wetlands Converted to Unvegetated Open Water Coastal Wetlands*.

20 Soil Carbon Stock Changes

21 Soil C stock changes are estimated for *Vegetated Coastal Wetlands Converted to Unvegetated Open Water Coastal*
 22 *Wetlands* on lands below the elevation of high tides (taken to be mean high water spring tide elevation) within the
 23 U.S. Land Representation according to the national LiDAR dataset, the national network of tide gauges and land use
 24 histories recorded in the 1996, 2001, 2005 and 2010 NOAA C-CAP surveys. Federal and non-federal lands are
 25 represented. Trends in land cover change are extrapolated to 1990 and 2015 from these datasets. C-CAP provides
 26 peer reviewed country-specific mapping to support IPCC Approach 3 quantification of coastal wetland distribution,
 27 including conversion to and from open water. Country-specific soil C stocks for mineral and organic soils, stratified
 28 by climate zones and wetland classes, are derived from a synthesis of peer-reviewed literature (Mangrove pool and
 29 removals data: *Cahoon & Lynch unpublished data; Lynch 1989; Callaway et al. 1997; Chen & Twilley 1999;*
 30 *McKee & Faulkner 2000; Ross et al. 2000; Chmura et al. 2003; Perry & Mendelsohn 2009; Castaneda-Moya et al.*
 31 *2013; Henry & Twilley 2013; Doughty et al. 2015; Marchio et al. 2016*. Tidal marsh pool and removals data:
 32 *Anisfeld unpublished data; Cahoon unpublished data; Cahoon & Lynch unpublished data; Chmura unpublished*
 33 *data; McCaffrey & Thomson 1980; Hatton 1981; Callaway et al. 1987; Craft et al. 1988; Cahoon & Turner 1989;*
 34 *Patrick & DeLaune 1990; Kearney & Stevenson 1991; Cahoon et al. 1996; Callaway et al. 1997; Roman et al. 1997;*
 35 *Bryant & Chabrek 1998; Orson et al. 1998; Markewich et al. 1998; Anisfeld et al. 1999; Connor et al. 2001; Choi*
 36 *& Wang 2001; Chmura et al. 2003, Hussein et al. 2004; Craft 2007; Miller et al. 2008; Drexler et al. 2009; Perry*
 37 *& Mendelsohn 2009; Loomis & Craft 2010; EPA's NWCA 2011; Callaway et al. 2012; Henry & Twilley 2013;*

1 *Weston et al. 2014*). For soil C stock change no differentiation is made between organic and mineral soils. Following
 2 the Tier 1 approach for estimating CO₂ emissions with extraction provided within the *Wetlands Supplement*, soil C
 3 loss with conversion of Vegetated Coastal Wetlands to Unvegetated Open Water Coastal Wetlands is assumed to
 4 affect soil C stock to one-meter depth with all emissions occurring in the year of wetland conversion, and multiplied
 5 by activity data of land area for management coastal wetlands. The methodology follows Eq. 4.6. Quantification of
 6 regional coastal wetland biomass stock changes for conversion of Vegetated Coastal Wetlands to Unvegetated Open
 7 Water Coastal Wetlands are in development and are not presented this year, though will be included in future
 8 reports.

9 *Soil Methane Emissions*

10 A Tier 1 assumption has been applied that salinity conditions are unchanged and hence methane emissions are
 11 assumed to be zero with conversion of Vegetated Coastal Wetlands to Unvegetated Open Water Coastal Wetlands.

12 **Uncertainty and Time-Series Consistency**

13 Underlying uncertainties in estimates of soil C stock changes associated with Tier 2 literature values of soil C
 14 stocks, assumptions that underlie the methodological approaches applied and uncertainties linked to interpretation of
 15 remote sensing data are included in this uncertainty assessment. Uncertainty specific to coastal wetlands include
 16 differentiation of palustrine and estuarine community classes, which determines the soil C stock applied. Soil C
 17 stocks applied are determined from vegetation community classes across the coastal zone and identified by NOAA
 18 C-CAP. Community classes are further subcategorized by climate zones and growth form (forest, shrub-scrub,
 19 marsh). Soil C stock data for all subcategories are not available and thus assumptions were applied using expert
 20 judgement about the most appropriate assignment of a soil C stock to a disaggregation of a community class.
 21 Because mean soil C stocks for each available community class are in a fairly narrow range, the same overall
 22 uncertainty was assigned to each (i.e., applying approach for asymmetrical errors, where the largest uncertainty for
 23 any one soil C stock referenced using published literature values for a community class; uncertainty approaches
 24 provide that if multiple values are available for a single parameter, the highest uncertainty value should be applied to
 25 the propagation of errors; IPCC 2000). Uncertainties for CH₄ flux are the Tier 1 default values reported in the
 26 *Wetlands Supplement*. Overall uncertainty of the NOAA C-CAP remote sensing product is 15 percent. This is in the
 27 range of remote sensing methods (±10-15 percent; IPCC 2003).

28 **Table 6-57: Approach 1 Quantitative Uncertainty Estimates for Net CO₂ Flux occurring**
 29 **within *Vegetated Coastal Wetlands Converted to Unvegetated Open Water Coastal Wetlands***
 30 **(MMT CO₂ Eq. and Percent)**

Source	2015 Flux Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Flux Estimate (MMT CO ₂ Eq.)			
		Lower Bound	Upper Bound	Lower Bound	Upper Bound
Combined Uncertainty for Flux Associated with Soil C Stock Change in <i>Vegetated Coastal Wetlands Converted to Unvegetated Open Water Coastal Wetlands</i>	3.5	2.1	5.0	-41.7%	41.7%

Note: Quality control measures are still underway and estimates will be finalized after public review.

31 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 32 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 33 above.

34 The C-CAP dataset, consisting of a time series of four time intervals, each five years in length, and two major
 35 hurricanes striking the Mississippi Delta in the most recent time interval (2006 to 2010), creates a challenge in
 36 utilizing it to represent the annual rate of wetland loss and for extrapolation to 1990 and 2015. Uncertainty in the
 37 defining the long term trend will be improved with release of the 2015 survey, expected in 2018 to 2019.

38 More detailed research is in development that provides a longer term assessment and more highly refined rates of
 39 wetlands loss across the Mississippi Delta (e.g., Couvillion et al, 2016), which could provide a more refined regional
 40 Approach 2-3 for assessing wetland loss and support the national scale assessment provided by CCAP.

1 Based upon the IPCC Tier 1 methodological guidance for estimating emissions with excavation in coastal wetlands,
2 it has been assumed that a 1 meter column of soil has been remobilized with erosion and the C released immediately.
3 This depth of disturbance is a simplifying assumption that is commonly applied in the scientific literature to gain a
4 first order estimate of scale of emissions (e.g., Delaune and White, 2012). It is also a simplifying assumption that all
5 that C is released back to the atmosphere immediately and future development of Tier 2 estimate may refine the
6 emissions both in terms of scale and rate. Given that erosion has been ongoing for multiple decades the assumption
7 that the C eroded is released to the atmosphere the year of erosion is a reasonable simplification that could be further
8 refined.

9 **QA/QC and Verification**

10 NOAA provided data (i.e., National LiDAR Dataset, NOS Tide Data, and C-CAP land cover and land cover change
11 mapping) undergo internal agency QA/QC procedures. Acceptance of final datasets into archive and dissemination
12 are contingent upon assurance that the data product is compliant with mandatory NOAA QA/QC requirements
13 (McCombs et al., 2016). QA/QC and Verification of the soil C stock dataset has been provided by the Smithsonian
14 Environmental Research Center and by the Coastal Wetlands project team leads who reviewed produced summary
15 tables against primary scientific literature. Land cover estimates were assessed to ensure that the total land area did
16 not change over the time series in which the inventory was developed, and verified by a second QA team. A team of
17 two evaluated and verified there were no computational errors within the calculation worksheets. Two
18 biogeochemists at the USGS also members of the NASA Carbon Monitoring System Science Team, corroborated
19 the assumption that where salinities are unchanged CH₄ emissions are constant with conversion of Unvegetated
20 Open Water Coastal Wetlands to Vegetated Coastal Wetlands.

21 **Planned Improvements**

22 A refined uncertainty analysis and efforts to improve times series consistency is planned for the 1990 to 2016
23 Inventory (2018 submission) or the 1990 to 2017 Inventory (2019 submission). An approach for calculating the
24 fraction of remobilized coastal wetland soil C returned to the atmosphere is currently under review and may be
25 included in future reports. Research by USGS is investigating higher resolution mapping approaches to quantify
26 conversion of coastal wetlands is also underway. Such approaches may form the basis of an Approach 3 land
27 representation assessment in future years.

28 **Removals from Unvegetated Open Water Coastal Wetlands** 29 **Converted to Vegetated Coastal Wetlands**

30 Open Water within the Land Representation is recognized as Wetlands within the Inventory. The appearance of
31 vegetated tidal wetlands on lands previously recognized as open water reflects either the building of new vegetated
32 marsh through sediment accumulation or the transition from other lands uses through an intermediary open water
33 stage as flooding intolerant plants are displaced and then replaced by wetland plants. Biomass and soil C
34 accumulation on *Unvegetated Open Water Coastal Wetlands Converted to Vegetated Coastal Wetlands* begins with
35 vegetation establishment.

36 Within the U.S., conversion of Unvegetated Open Water Coastal Wetlands to Vegetated Coastal Wetlands is
37 predominantly due to engineered activities, which include active restoration of wetlands (e.g., wetlands restoration
38 in San Francisco Bay), dam removals or other means to reconnect sediment supply to the nearshore (e.g.,
39 Atchafalaya Delta, Louisiana, Couvillion et al., 2011). Wetlands restoration projects have been ongoing in the U.S.
40 since the 1970s. Early projects were small, a few hectares in size. By the 1990s, restoration projects, each hundreds
41 of hectares in size, were becoming common in major estuaries. In a number of coastal areas e.g., San Francisco Bay,
42 Puget Sound, Mississippi Delta and south Florida, restoration activities are in planning and implementation phases,
43 each with the goal of recovering tens of thousands of hectares of wetlands.

44 During wetland restoration, Unvegetated Open Water Coastal Wetland is a common intermediary phase bridging
45 land use transitions from Cropland or Grassland to Vegetated Coastal Wetlands. The time period of open water may
46 last from five to 20 years depending upon the conditions. The conversion of these other land uses to Unvegetated
47 Open Water Coastal Wetland will result in reestablishment of wetland biomass and soil C sequestration and may

1 result in cessation of emissions from drained organic soil. Only changes in soil C stocks are reported in the
 2 Inventory at this time, but improvements are being evaluated to include changes from other C pools.

3 **Table 6-58: Net CO₂ Flux from Soil C Stock Changes from *Unvegetated Open Water Coastal*
 4 *Wetlands Converted to Vegetated Coastal Wetlands* (MMT CO₂ Eq.)**

Year	1990	2005	2011	2012	2013	2014	2015
Net Soil Flux	(0.01)	(0.004)	(0.01)	(0.01)	(0.01)	(0.01)	(0.01)

Note: Parentheses indicate net sequestration.

Estimates prior to 1996 and after 2010 are extrapolated based on C-CAP data and therefore may not fully reflect changes occurring in the latter part of the time series. Mineral and Organic Soils are not differentiated in terms of C removals.

5 **Table 6-59: Net CO₂ Flux from Soil C Stock Changes from *Unvegetated Open Water Coastal*
 6 *Wetlands Converted to Vegetated Coastal Wetlands* (MMT C)**

Year	1990	2005	2011	2012	2013	2014	2015
Net Soil Flux	(0.002)	(0.001)	(0.002)	(0.002)	(0.002)	(0.002)	(0.002)

Note: Parentheses indicate net sequestration.

Estimates prior to 1996 and after 2010 are extrapolated based on C-CAP data and therefore may not fully reflect changes occurring in the latter part of the time series. Mineral and Organic Soils are not differentiated in terms of C removals.

7 Methodology

8 The following section includes a brief description of the methodology used to estimate changes in soil C stocks and
 9 CH₄ emissions for *Unvegetated Open Water Coastal Wetlands Converted to Vegetated Coastal Wetlands*.

10 *Soil Carbon Stock Change*

11 Soil C removals are estimated for *Unvegetated Open Water Coastal Wetlands Converted to Vegetated Coastal*
 12 *Wetlands* on lands below the elevation of high tides (taken to be mean high water spring tide elevation) within the
 13 U.S. Land Representation according to the national LiDAR dataset, the national network of tide gauges and land use
 14 histories recorded in the 1996, 2001, 2005 and 2010 NOAA C-CAP surveys. Federal and non-federal lands are
 15 represented. Trends in land cover change are extrapolated to 1990 and 2015 from these datasets. C-CAP provides
 16 peer reviewed Tier 2 level mapping of coastal wetland distribution, including conversion to and from open water.
 17 Country-specific soil C stock change associated with soil C accretion, stratified by climate zones and wetland
 18 classes, are derived from a synthesis of peer-reviewed literature (Mangrove pool and removals data: *Cahoon &*
 19 *Lynch unpublished data; Lynch 1989; Callaway et al. 1997; Chen & Twilley 1999; McKee & Faulkner 2000; Ross*
 20 *et al. 2000; Chmura et al. 2003; Perry & Mendelssohn 2009; Castaneda-Moya et al. 2013; Henry & Twilley 2013;*
 21 *Doughty et al. 2015; Marchio et al. 2016.* Tidal marsh pool and removals data: *Anisfeld unpublished data; Cahoon*
 22 *unpublished data; Cahoon & Lynch unpublished data; Chmura unpublished data; McCaffrey & Thomson 1980;*
 23 *Hatton 1981; Callaway et al. 1987; Craft et al. 1988; Cahoon & Turner 1989; Patrick & DeLaune 1990; Kearney*
 24 *& Stevenson 1991; Cahoon et al. 1996; Callaway et al. 1997; Roman et al. 1997; Bryant & Chabrek 1998; Orson et*
 25 *al. 1998; Markewich et al. 1998; Anisfeld et al. 1999; Connor et al. 2001; Choi & Wang 2001; Chmura et al. 2003,*
 26 *Hussein et al. 2004; Craft 2007; Miller et al. 2008; Drexler et al. 2009; Perry & Mendelssohn 2009; Loomis &*
 27 *Craft 2010; EPA's NWCA 2011; Callaway et al. 2012; Henry & Twilley 2013; Weston et al. 2014).*). Soil C
 28 removals are stratified based upon wetland class (Estuarine, Palustrine) and subclass, (Emergent Marsh, Scrub
 29 Shrub). For soil C stock change no differentiation is made for soil type.

30 Tier 2 level estimates of CO₂ removals associated with annual soil C accumulation in managed Vegetated Coastal
 31 Wetlands were developed using country-specific soil C removal factors multiplied by activity data on land area for
 32 management coastal wetlands. The methodology follows Eq. 4.7, Chapter 4 of the *Wetlands Supplement*, and
 33 applied to the area of managed Vegetated Coastal Wetlands on an annual basis. Emission factors were developed
 34 from literature references that provided soil C removal factors disaggregated by climate region and vegetation type
 35 by salinity range (estuarine or palustrine) as identified using NOAA C-CAP as described above. Quantification of

1 regional coastal wetland biomass C stock changes for perennial vegetation are in development and are not presented
 2 this year, though will be included in future reports.

3 *Soil Methane Emissions*

4 A Tier 1 assumption has been applied that salinity conditions are unchanged and hence methane emissions are
 5 assumed to be zero with conversion of Vegetated Open Water Coastal Wetlands to Vegetated Coastal Wetlands.

6 **Uncertainty and Time-Series Consistency**

7 Underlying uncertainties in estimates of soil C stock changes and methane emissions include error in uncertainties
 8 associated with Tier 2 literature values of soil C stocks and methane flux and assumptions that underlie the
 9 methodological approaches applied and uncertainties linked to interpretation of remote sensing data. Uncertainty
 10 specific to coastal wetlands include differentiation of palustrine and estuarine community classes which determines
 11 the soil C stock and methane flux applied. Soil C stocks and methane fluxes applied are determined from vegetation
 12 community classes across the coastal zone and identified by NOAA C-CAP. Community classes are further
 13 subcategorized by climate zones and growth form (forest, shrub-scrub, marsh). Soil C stock data for all
 14 subcategories are not available and thus assumptions were applied using expert judgement about the most
 15 appropriate assignment of a soil C stock to a disaggregation of a community class. Because mean soil C stocks for
 16 each available community class are in a fairly narrow range, the same overall uncertainty was applied to each (i.e.,
 17 applying approach for asymmetrical errors, where the largest uncertainty for any one soil C stock referenced using
 18 published literature values for a community class; uncertainty approaches provide that if multiple values are
 19 available for a single parameter, the highest uncertainty value should be applied to the propagation of errors; IPCC
 20 2000). Uncertainties for CH₄ flux are the Tier 1 default values reported in the *Wetlands Supplement*. Overall
 21 uncertainty of the NOAA C-CAP remote sensing product is 15 percent. This is in the range of remote sensing
 22 methods (±10-15 percent; IPCC 2003). Uncertainties for methane flux include the Tier 1 default values reported in
 23 the *Wetlands Supplement* along with the overall uncertainty of the NOAA C-CAP remote sensing product, which is
 24 estimated at 15 percent. This is in the typical range of remote sensing methods (±10-15; GPG LULUCF, Chapter 3).
 25 However, there is significant uncertainty in salinity ranges for tidal and non-tidal estuarine wetlands and activity
 26 data used to develop the methane flux (delineation of an 18 ppt boundary) and will need significant improvement to
 27 reduce uncertainties.

28 **Table 6-60: Approach 1 Quantitative Uncertainty Estimates for C Stock Changes occurring**
 29 **within *Unvegetated Open Water Coastal Wetlands Converted to Vegetated Coastal Wetlands***
 30 **(MMT CO₂ Eq. and Percent)**

Source	2015 Flux Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Flux Estimate (MMT CO ₂ Eq.)			
		Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Combined Uncertainty for Flux Associated with Wetlands Soil C Stock Change in <i>Unvegetated Open Water Coastal Wetlands Converted to Vegetated Coastal Wetlands</i>	(0.009)	(0.012)	(0.006)	-29.5%	29.5%

Notes: Parentheses indicate net sequestration. Quality control measures are still underway and estimates will be finalized after public review.

31 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 32 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 33 above.

34 **QA/QC and Verification**

35 NOAA provided data (i.e., National LiDAR Dataset, NOS Tide Data, and C-CAP land cover and land cover change
 36 mapping) undergo internal agency QA/QC assessment procedures. Acceptance of final datasets into the archive for
 37 dissemination are contingent upon assurance that the product is compliant with mandatory NOAA QA/QC
 38 requirements (McCombs et al., 2016). QA/QC and Verification of soil C stock dataset has been provided by the

1 Smithsonian Environmental Research Center and Coastal Wetlands project team leads who reviewed produced
 2 summary tables against primary scientific literature. Land cover estimates were assessed to ensure that the total land
 3 area did not change over the time series in which the inventory was developed, and verified by a second QA team. A
 4 team of two evaluated and verified there were no computational errors within calculation worksheets. Two
 5 biogeochemists at the USGS, also members of the NASA Carbon Monitoring System Science Team, corroborated
 6 the simplifying assumption that where salinities are unchanged CH₄ emissions are constant with conversion of
 7 Unvegetated Open Water Coastal Wetlands to Vegetated Coastal Wetlands.

8 **Planned Improvements**

9 A USGS/ NASA Carbon Monitoring System Carbon is in progress to establish a U.S. country-specific database of
 10 published measurement data quantifying soil C stock, wetland biomass and methane emissions. Refined error
 11 analysis combining land cover change and soil and biomass C stock estimates will be provided. Under this
 12 investigation a model is in development to represent changes in soil C stocks. This investigation is to be completed
 13 by November 2017 and may be included in either the 1990 to 2016 Inventory (2018 submission) or the 1990 to 2017
 14 Inventory (2019 submission).

15 **N₂O Emissions from Aquaculture in Coastal Wetlands**

16 Shrimp and fish cultivation in coastal areas increases nitrogen loads resulting in direct emissions of N₂O. Nitrous
 17 oxide is generated and emitted as a by-product of the conversion of ammonia (contained in fish urea) to nitrate
 18 through nitrification and nitrate to N₂ gas through denitrification (Hu et al., 2012). Nitrous oxide emissions can be
 19 readily estimated from data on fish production (IPCC 2013 *Wetlands Supplement*).

20 Overall, aquaculture production in the U.S. has fluctuated slightly from year to year though it is essentially at a
 21 similar level since 2011 as in baseline year of 1990. Data for 2015 are not yet available and emissions have been
 22 held constant with 2014 at 0.14 MMT CO₂ Eq).

23 **Table 6-61: Net N₂O Flux from Aquaculture in Coastal Wetlands (MMT CO₂ Eq.)**

Year	1990	2005	2011	2012	2013	2014	2015
Flux	0.13	0.18	0.14	0.14	0.14	0.14	0.14

Note: Estimates are derived from NOAA Fisheries, Fisheries Statistics Division. All reported aquaculture production for coastal areas is included in calculation with the exception of clams, mussels and oysters, for which no applied food stock is assumed. Data for 2015 has yet to be published, value held constant with recent years.

24 **Table 6-62: Net N₂O Flux from Aquaculture in Coastal Wetlands (kt N₂O)**

Year	1990	2005	2011	2012	2013	2014	2015
Flux	0.44	0.59	0.47	0.46	0.48	0.47	0.47

Note: Estimates are derived from NOAA Fisheries, Fisheries Statistics Division. All reported aquaculture production in coastal areas is included in calculation with the exception of clams, mussels and oysters, for which no applied food stock is assumed. Data for 2015 has yet to be published, value held constant with recent years.

25 **Methodology**

26 The methodology to estimate N₂O emissions from Aquaculture in Coastal Wetlands follows guidance in the 2013
 27 *IPCC Wetlands Supplement* applying country-specific fisheries production data and the IPCC Tier 1 default
 28 emission factor.

1 Each year NOAA Fisheries document the status of U.S. marine fisheries in the annual report of *Fisheries of the*
 2 *United States*, from which activity data for this analysis is derived.⁶⁹ The fisheries report has been produced in
 3 various forms for more than 100 years, primarily at the national level, on U.S. recreational catch and commercial
 4 fisheries landings and values. In addition, data are reported on U.S. aquaculture production, the U.S. seafood
 5 processing industry, imports and exports of fish-related products, and domestic supply and per capita consumption
 6 of fisheries products. Within the aquaculture chapter mass of production for Catfish, Striped bass, Tilapia, Trout,
 7 Crawfish, Salmon and Shrimp are reported. While some of these fisheries are produced on land and some in open
 8 water cages, all have data on the quantity of food stock produced, which is the activity data that is applied to the
 9 IPCC Tier 1 default emissions factor to estimate emissions of N₂O from aquaculture. It is not apparent from the data
 10 as to the extent of aquaculture occurring above the extent of high tides on river floodplains. While some aquaculture
 11 likely occurs on coastal lowland floodplains this is likely a minor component of tidal aquaculture production at
 12 because of the need a regular source of water for pond flushing. The estimation of N₂O emissions from aquaculture
 13 is not sensitive to salinity using IPCC approaches and as such the location of aquaculture ponds on the landscape
 14 does not influence the calculations.

15 Other open water shellfisheries for which no food stock is provided, and thus no additional N inputs, are not
 16 applicable for estimating N₂O emissions (e.g., Clams, Mussels and Oysters) have not been included in the analysis.
 17 The IPCC Tier 1 default emissions factor of 0.00169 kg N₂O-N per kg of fish produced (95 percent confidence
 18 interval – 0,0038) is applied to the activity data to calculate total N₂O emissions. The AR4 global warming potential
 19 value of 298 is applied in deriving CO₂ Eq. values from N₂O emissions.

20 Uncertainty and Time-Series Consistency

21 Uncertainty estimates are based upon the Tier 1 default 95 percent confidence interval provided within the *Wetlands*
 22 *Supplement* for N₂O emissions. Uncertainties in N₂O emissions from aquaculture are based on expert judgement for
 23 the NOAA *Fisheries of the United States* fisheries production data (± 100 percent) multiplied by default uncertainty
 24 level for N₂O emissions found in Table 4.15, chapter 4 of the *Wetlands Supplement*. Given the overestimate of
 25 fisheries production from coastal wetland areas due to the inclusion of fish production in non-coastal wetland areas,
 26 this is a reasonable initial first approximation for an uncertainty range.

27 **Table 6-63: Approach 1 Quantitative Uncertainty Estimates for N₂O Emissions for**
 28 **Aquaculture Production in Coastal Wetlands (MMT CO₂ Eq. and Percent)**

Source	2015 Flux Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emissions Estimate ^a (MMT CO ₂ Eq.)			
		Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Combined Uncertainty for Flux Associated with N ₂ O Emissions for Aquaculture Production in Coastal Wetlands	0.14	(0.02)	0.30	-116%	116%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

29 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 30 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 31 above.

32 QA/QC and Verification

33 NOAA provide internal QA/QC review of reported fisheries data. The Coastal Wetlands Inventory team consulted
 34 with the Coordinating Lead Authors of the Coastal Wetlands chapter, *IPCC 2013 Wetlands Supplement* on which
 35 fisheries production to include in reporting. It was concluded that N₂O emissions estimates should be applied to any
 36 fish production to which food supplement is supplied by they pond or open water and that salinity conditions was
 37 not a determining factor in N₂O emissions.

⁶⁹ See <<https://www.st.nmfs.noaa.gov/st1/publications.html>>

6.9 Land Converted to Wetlands (IPCC Source Category 4D2)

Emissions and Removals from Land Converted to Vegetated Coastal Wetlands

Land Converted to Vegetated Coastal Wetlands occur as a result of inundation of unprotected low-lying coastal areas with gradual sea level rise, flooding of previously drained land behind hydrological barriers, and through active restoration and creation of coastal wetlands through removal of hydrological barriers. All other land categories are identified has having some area converting to Vegetated Coastal Wetlands. Between 1990 and 2015 the rate of annual transition for *Land Converted to Vegetated Coastal Wetlands* ranged from 2,619 ha/year to 5,316 ha/year. Conversion rates were higher during the period 2010 through 2015 than during the earlier part of the time series, driven an increase in the extent unvegetated lands bear ground in *Other Land Converted to Wetlands*.

However, at the present stage of Inventory development, Coastal Wetlands are not explicitly shown in the Land Representation analysis while work continues harmonizing data from NOAA’s Coastal Change Analysis Program⁷⁰ with NRI data used to compile the Land Representation. As a QC step a check was undertaken to confirm that Coastal Wetlands recognized by C-CAP represented a subset of Wetlands recognized by the NRI for marine coastal states. Delineating Vegetated Coastal Wetlands from ephemerally flooded upland Grasslands represents a particular challenge in remote sensing. Moreover, at the boundary between wetlands and uplands, which may be gradual on low lying coastlines, the presence of wetlands may be ephemeral depending upon whether and climate cycles and as such the emissions and removals will also vary over such time frames.

Following conversion to Vegetated Coastal Wetlands there are increases in biomass and soil C storage. Additionally, at salinities less than half that of seawater the transition from upland dry soils to wetland soils results in CH₄ emissions. In this Inventory analysis, soil C stock changes and CH₄ emissions are quantified. Estimates of biomass C stock changes will be included in subsequent reports. Estimates of emissions and removals are based on emission factor data that have been applied to estimate changes in soil C stock for *Land Converted to Vegetated Coastal Wetlands*.

Table 6-64: Net CO₂ Flux from Soil C Stock Changes in *Land Converted to Vegetated Coastal Wetlands* (MMT CO₂ Eq.)

Year	1990	2005	2010	2011	2012	2013	2014	2015

4 Methodology

5 The following section includes a brief description of the methodology used to estimate changes in soil C removals
 6 and CH₄ emissions for *Land Converted to Vegetated Coastal Wetlands*.

7 Soil Carbon Stock Changes

8 Soil C removals are estimated for *Land Converted to Vegetated Coastal Wetlands* for land below the elevation of
 9 high tides (taken to be mean high water spring tide elevation) and as far seawards as the extent of intertidal vascular
 10 plants within the U.S. Land Representation according to the national LiDAR dataset, the national network of tide
 11 gauges and land use histories recorded in the 1996, 2001, 2005 and 2010 NOAA C-CAP surveys.⁷¹ As noted above,
 12 the NOAA C-CAP dataset has yet to be harmonized with the NRI dataset from which the Land Representation is
 13 derived. Federal and non-federal lands are represented. Trends in land cover change are extrapolated to 1990 and
 14 2015 from these datasets. Based upon NOAA C-CAP, wetlands are subdivided into freshwater (Palustrine) and
 15 saline (Estuarine) classes and further subdivided into Emergent marsh, scrub shrub and forest classes. Soil C stock
 16 changes, stratified by climate zones and wetland classes, are derived from a synthesis of peer-reviewed literature
 17 (Mangrove pool and removals data: *Cahoon & Lynch unpublished data; Lynch 1989; Callaway et al. 1997; Chen &*
 18 *Twilley 1999; McKee & Faulkner 2000; Ross et al. 2000; Chmura et al. 2003; Perry & Mendelsohn 2009;*
 19 *Castaneda-Moya et al. 2013; Henry & Twilley 2013; Doughty et al. 2015; Marchio et al. 2016*. Tidal marsh pool
 20 and removals data: *Anisfeld unpublished data; Cahoon unpublished data; Cahoon & Lynch unpublished data;*
 21 *Chmura unpublished data; McCaffrey & Thomson 1980; Hatton 1981; Callaway et al. 1987; Craft et al. 1988;*
 22 *Cahoon & Turner 1989; Patrick & DeLaune 1990; Kearney & Stevenson 1991; Cahoon et al. 1996; Callaway et al.*
 23 *1997; Roman et al. 1997; Bryant & Chabrek 1998; Orson et al. 1998; Hussein et al. 1998; Markewich et al. 1999;*
 24 *Connor et al. 2001; Choi & Wang 2001; Chmura et al. 2003, Hussein et al. 2004; Craft 2007; Miller et al. 2008;*
 25 *Drexler et al. 2009; Perry & Mendelsohn 2009; Loomis & Craft 2010; EPA's NWCA 2011; Callaway et al. 2012;*
 26 *Henry & Twilley 2013; Weston et al. 2014*). To estimate soil C stock changes no differentiation is made for soil
 27 type.

28 Tier 2 level estimates of soil C removal associated with annual soil C accumulation from *Land Converted to*
 29 *Vegetated Coastal Wetlands* were developed using country-specific soil C removal factors multiplied by activity
 30 data of land area for *Land Converted to Vegetated Coastal Wetlands*. The methodology follows Eq. 4.7, Chapter 4
 31 of the *Wetlands Supplement*, and applied to the area of *Land Converted to Vegetated Coastal Wetlands* on an annual
 32 basis. Emission factors were developed from literature references that provided soil C removal factors disaggregated
 33 by climate region, vegetation type by salinity range (estuarine or palustrine) as identified using NOAA C-CAP as

⁷¹ See <<https://coast.noaa.gov/digitalcoast/tools/lca>>.

1 described above. Quantification of regional coastal wetland biomass C stock changes for perennial vegetation are in
 2 development and are not presented this year, though will be included in future reports.

3 **Soil Methane Emissions**

4 Tier 1 estimates of CH₄ emissions for *Vegetated Coastal Wetlands Remaining Vegetated Coastal Wetlands* are
 5 derived from the same wetland map used to in the analysis of wetland soil C fluxes, produced from C-CAP, LiDAR
 6 and tidal data, in combination with default CH₄ emission factors provided in Table 4.14 of the *Wetlands Supplement*.
 7 The methodology follows Eq. 4.9, Chapter 4 of the *Wetlands Supplement*, and is applied to the total area of *Land*
 8 *Converted to Vegetated Coastal Wetlands* on an annual basis. The AR4 global warming potential factor of 25 was
 9 used in converting CH₄ to CO₂ Eq. values.

10 **Uncertainty and Time-Series Consistency**

11 Underlying uncertainties in estimates of soil C removal factors and CH₄ include error in uncertainties associated
 12 with Tier 2 literature values of soil C removal estimates and CH₄ flux, assumptions that underlie the methodological
 13 approaches applied and uncertainties linked to interpretation of remote sensing data.

14 Uncertainty specific to coastal wetlands include differentiation of palustrine and estuarine community classes which
 15 determines the soil C removal and CH₄ flux applied. Soil C removal and CH₄ fluxes applied are determined from
 16 vegetation community classes across the coastal zone and identified by NOAA C-CAP. Community classes are
 17 further subcategorized by climate zones and growth form (forest, shrub-scrub, marsh). Soil C removal data for all
 18 subcategories are not available and thus assumptions were applied using expert judgement about the most
 19 appropriate assignment of a soil C removal factor to a disaggregation of a community class. Because mean soil C
 20 removal for each available community class are in a fairly narrow range, the same overall uncertainty was assigned
 21 to each, (i.e., applying approach for asymmetrical errors, where the largest uncertainty for any one soil C stock
 22 referenced using published literature values for a community class; uncertainty approaches provide that if multiple
 23 values are available for a single parameter, the highest uncertainty value should be applied to the propagation of
 24 errors; IPCC 2000). Uncertainties for CH₄ flux are the Tier 1 default values reported in the *Wetlands Supplement*.
 25 Overall uncertainty of the NOAA C-CAP remote sensing product is 15 percent. This is in the range of remote
 26 sensing methods (±10-15 percent; IPCC 2003). However, there is significant uncertainty in salinity ranges for tidal
 27 and non-tidal estuarine wetlands and activity data used to estimate the apply CH₄ flux (e.g., delineation of an 18 ppt
 28 boundary) which will need significant improvement to reduce uncertainties.

29 **Table 6-68: Approach 1 Quantitative Uncertainty Estimates for Net CO₂ Flux Changes**
 30 **occurring within *Land Converted to Vegetated Coastal Wetlands* (MMT CO₂ Eq. and Percent)**

Source	2015 Flux Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Flux Estimate ^a (MMT CO ₂ Eq.)			
		Lower Bound	Upper Bound	Lower Bound	Upper Bound

^a Range of flux estimates based on error propagation at 95 percent confidence interval.

Note: Quality control measures are still underway and estimates will be finalized after public review.

Conversion of Vegetated Lands to Vegetated Coastal Wetlands is a particular challenge for recognition by remote sensing. Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

QA/QC and Verification

NOAA provided National LiDAR Dataset, tide data, and C-CAP land cover and land cover change mapping, all of which are subject to agency internal QA/QC assessment. Acceptance of final datasets into archive and dissemination are contingent upon the product compilation are compliant with mandatory QA/QC requirements (McCombs, et al., 2016). QA/QC and verification of soil C stock dataset has been provided by the Smithsonian Environmental Research Center and Coastal Wetland Inventory team leads who reviewed summary tables against reviewed sources. Land cover estimates were assessed to ensure that the total land area did not change over the time series in which the inventory was developed, and verified by a second QA team. A team of two evaluated and verified there were no computational errors within the calculation worksheets. Soil C stock, emissions/removals data were based upon peer-reviewed literature and CH₄ emission factors derived from the IPCC Wetlands Supplement.

Planned Improvements

A USGS/ NASA Carbon Monitoring System investigation is in progress to establish a U.S. country-specific database of soil C stocks, wetland biomass and CH₄ emissions. Refined error analysis combining land cover change and C stock estimates will be provided. Under this investigation, a model is in development to represent changes in soil C stocks. This investigation is due to be completed by November 2017. Future improvements will thus include estimates of biomass C stock change with *Land Converted to Vegetated Coastal Wetlands*.

6.10 Settlements Remaining Settlements

Soil Carbon Stock Changes (IPCC Source Category 3B5a)

Drainage of organic soils is common when wetland areas have been developed for settlements. Organic soils, also referred to as *Histosols*, include all soils with more than 12 to 20 percent organic C by weight, depending on clay content (NRCS 1999, Brady and Weil 1999). The organic layer of these soils can be very deep (i.e., several meters), and form under inundated conditions that results in minimal decomposition of plant residues. Drainage of organic soils leads to aeration of the soil that accelerates decomposition rate and CO₂ emissions.⁷² Due to the depth and richness of the organic layers, C loss from drained organic soils can continue over long periods of time, which varies depending on climate and composition (i.e., decomposability) of the organic matter (Armentano and Menges 1986).

⁷² N₂O emissions from soils are included in the N₂O Fluxes from Settlement Soils section.

1 The United States does not estimate changes in soil organic C stocks for mineral soils on *Settlements Remaining*
 2 *Settlements*, which is consistent with the assumption of the Tier 1 method in the IPCC guidelines (2006). This
 3 assumption may be evaluated in the future if funding and resources are available to conduct an analysis of soil C
 4 stock changes in mineral soils of *Settlements Remaining Settlements*.

5 *Settlements Remaining Settlements* includes all areas that have been settlements for a continuous time period of at
 6 least 20 years according to the 2012 United States Department of Agriculture (USDA) National Resources Inventory
 7 (NRI) (USDA-NRCS 2015)⁷³ or according to the National Land Cover Dataset for federal lands (Homer et al. 2007;
 8 Fry et al. 2011; Homer et al. 2015). The Inventory includes settlements on privately-owned lands in the
 9 conterminous United States and Hawaii. Alaska and the small amount of settlements on federal lands are not
 10 included in this Inventory even though these areas are part of the U.S. managed land base. This leads to a
 11 discrepancy with the total amount of managed area in *Settlements Remaining Settlements* (see Section 6.1
 12 Representation of the U.S. Land Base) and the settlements area included in the Inventory analysis. There is a
 13 planned improvement to include settlements on organic soils in these areas as part of a future Inventory.

14 CO₂ emissions from drained organic soils in settlements are 1.4 MMT CO₂ Eq. (0.4 MMT C) in 2015. Although the
 15 flux is relatively small, the amount has increased by over 850 percent since 1990.

16 **Table 6-70: Net CO₂ Flux from Soil C Stock Changes in *Settlements Remaining Settlements***
 17 **(MMT CO₂ Eq.)**

Soil Type	1990	2005	2011	2012	2013	2014	2015
Organic Soils	0.1	0.5	1.3	1.3	1.3	1.3	1.4

Note: Estimates after 2012 are based on NRI data from 2012 and therefore may not fully reflect changes occurring in the latter part of the time series.

18 **Table 6-71: Net CO₂ Flux from Soil C Stock Changes in *Settlements Remaining Settlements***
 19 **(MMT C)**

Soil Type	1990	2005	2011	2012	2013	2014	2015
Organic Soils	+	0.1	0.3	0.4	0.4	0.4	0.4

+ Does not exceed 0.05 MMT C

Note: Estimates after 2012 are based on NRI data from 2012 and therefore may not fully reflect changes occurring in the latter part of the time series.

20 Methodology

21 The IPCC Tier 2 method is used to estimate soil organic C stock changes for organic soils in *Settlements Remaining*
 22 *Settlements* (IPCC 2006). The Tier 1 method assumes that soil organic C stocks in mineral soils are not changing
 23 (i.e., C inputs are equal to C outputs). The Tier 2 method assumes that organic soils are losing C at a rate similar to
 24 croplands, and therefore uses the country-specific values for cropland (Ogle et al. 2003). The following section
 25 includes a description of the methodology, including (1) determination of the land base that is classified as
 26 settlements; and (2) estimation of emissions from drained organic soils.

27 The land area designated as settlements is based primarily on the 2012 National Resources Inventory (NRI) (USDA
 28 2015) with additional information from the National Land Cover Dataset (NLCD) (Fry et al. 2011; Homer et al.
 29 2007; Homer et al. 2015). It is assumed that all settlement area on organic soils is drained, and those areas are
 30 provided in Table 6-72 (See Section 0, Representation of the U.S. Land Base for more information). The area of
 31 drained organic soils in *Settlements Remaining Settlements* is estimated from the NRI spatial weights and aggregated
 32 to the country (Table 6-72). The area of land on organic soils in *Settlements Remaining Settlements* has increased
 33 from 3 thousand hectares in 1990 to over 28 thousand hectares in 2015.

⁷³ NRI survey locations are classified according to land-use histories starting in 1979, and consequently the classifications are based on less than 20 years from 1990 to 1998. This may have led to an overestimation of *Settlements Remaining Settlements* in the early part of the time series to the extent that some areas are converted to settlements between 1971 and 1978.

Table 6-72: Thousands of Hectares of Drained Organic Soils in *Settlements Remaining Settlements*

Year	Area (Thousand Hectares)
1990	3
2005	10
2011	26
2012	28
2013	28
2014	28
2015	28

Notes: Estimates after 2012 are based on NRI data from 2012 and therefore may not fully reflect changes occurring in the latter part of the time series.

To estimate CO₂ emissions from drained organic soils, the total area of organic soils in *Settlements Remaining Settlements* is multiplied by the country-specific emission factors for *Cropland Remaining Cropland* under the assumption that there is deep drainage of the soils. The emission factors are 11.2 MMT C per ha in cool temperate regions, 14.0 MMT C per ha in warm temperate regions, and 11.2 MMT C per ha in subtropical regions (See Annex 3.12 for more information).

Uncertainty and Time-Series Consistency

The results of the Approach 2 Monte Carlo uncertainty analysis are summarized in Table 6-73. Soil C losses from drained organic soils in *Settlements Remaining Settlements* for 2015 are estimated to be between 0.7 and 2.3 MMT CO₂ Eq. at a 95 percent confidence level. This indicates a range of 47 percent below and 67 percent above the 2015 emission estimate of 1.4 MMT CO₂ Eq.

Table 6-73: Uncertainty Estimates for CO₂ Emissions from Drained Organic Soils in *Settlements Remaining Settlements* (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Organic Soils	CO ₂	1.4	0.7	2.3	-47%	67%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section, above.

QA/QC and Verification

Quality control measures included checking input data, model scripts, and results to ensure data are properly handled throughout the inventory process. Inventory reporting forms and text are reviewed and revised as needed to correct transcription errors.

1 **Planned Improvements**

2 This source will be extended to include CO₂ emissions from drainage of organic soils in settlements of Alaska and
3 federal lands in order to provide a complete inventory of emissions for this category.

4 **Changes in Carbon Stocks in Urban Trees (IPCC Source** 5 **Category 4E1)**

6 Urban forests constitute a significant portion of the total U.S. tree canopy cover (Dwyer et al. 2000). Urban areas
7 (cities, towns, and villages) are estimated to cover over 3 percent of the United States (U.S. Census Bureau 2012).
8 With an average tree canopy cover of 35 percent, urban areas account for approximately 5 percent of total tree cover
9 in the continental United States (Nowak and Greenfield 2012). Trees in urban areas of the United States were
10 estimated to account for an average annual net sequestration of 77.0 MMT CO₂ Eq. (21.0 MMT C) over the period
11 from 1990 through 2015. Net C flux from urban trees in 2015 was estimated to be -91.7 MMT CO₂ Eq. (-25.0 MMT
12 C). Annual estimates of CO₂ flux (Table 6-74) were developed based on periodic (1990, 2000, and 2010) U.S.
13 Census data on urbanized area. The estimate of urbanized area is smaller than the area categorized as *Settlements* in
14 the Representation of the U.S. Land Base developed for this report: over the 1990 through 2015 time series the
15 Census urban area totaled, on average, about 63 percent of the *Settlements* area.

16 In 2015, Census urban area totaled about 68 percent of the total area defined as *Settlements*. Census area data are
17 preferentially used to develop C flux estimates for this source category since these data are more applicable for use
18 with the available peer-reviewed data on urban tree canopy cover and urban tree C sequestration. Annual
19 sequestration increased by 52 percent between 1990 and 2015 due to increases in urban land area. Data on C storage
20 and urban tree coverage were collected since the early 1990s and have been applied to the entire time series in this
21 report. As a result, the estimates presented in this chapter are not truly representative of changes in C stocks in urban
22 trees for *Settlements* areas, but are representative of changes in C stocks in urban trees for Census urban area. The
23 method used in this report does not attempt to scale these estimates to the *Settlements* area. Therefore, the estimates
24 presented in this chapter are likely an underestimate of the true changes in C stocks in urban trees in all *Settlements*
25 areas—i.e., the changes in C stocks in urban trees presented in this chapter are a subset of the changes in C stocks in
26 urban trees in all *Settlements* areas.

27 Urban trees often grow faster than forest trees because of the relatively open structure of the urban forest (Nowak
28 and Crane 2002). Because tree density in urban areas is typically much lower than in forested areas, the C storage
29 per hectare of land is in fact smaller for urban areas than for forest areas. To quantify the C stored in urban trees, the
30 methodology used here requires analysis per unit area of tree cover, rather than per unit of total land area (as is done
31 for Forestlands). Expressed in this way per unit of tree cover, areas covered by urban trees actually have a greater C
32 density than do forested areas (Nowak and Crane 2002). Expressed per unit of land area, however, the situation is
33 the opposite: because tree density is so much lower in urban areas, these areas have a smaller C density per unit land
34 area than forest areas.

1 **Table 6-74: Net C Flux from Urban Trees (MMT CO₂ Eq. and MMT C)**

Year	MMT CO ₂ Eq.	MMT C
1990	(60.4)	(16.5)
2005	(80.5)	(22.0)
2011	(87.3)	(23.8)
2012	(88.4)	(24.1)
2013	(89.5)	(24.4)
2014	(90.6)	(24.7)
2015	(91.7)	(25.0)

Note: Parentheses indicate net sequestration.

2 **Methodology**

3 Methods for quantifying urban tree biomass, C sequestration, and C emissions from tree mortality and
 4 decomposition were taken directly from Nowak et al. (2013), Nowak and Crane (2002), and Nowak (1994). In
 5 general, the methodology used by Nowak et al. (2013) to estimate net C sequestration in urban trees followed three
 6 steps, each of which is explained further in the paragraphs below. First, field data from cities and states were used to
 7 estimate C in urban tree biomass from field data on measured tree dimensions. Second, estimates of annual tree
 8 growth and biomass increment were generated from published literature and adjusted for tree condition, crown
 9 competition, and growing season to generate estimates of gross C sequestration in urban trees for all 50 states and
 10 the District of Columbia. Third, estimates of C emissions due to mortality and decomposition were subtracted from
 11 gross C sequestration values to derive estimates of net C sequestration.

12 For this Inventory report, net C sequestration estimates for all 50 states and the District of Columbia, that were
 13 generated using the Nowak et al. (2013) methodology and expressed in units of C sequestered per unit area of tree
 14 cover, were then used to estimate urban tree C sequestration in the United States. To accomplish this, we used urban
 15 area estimates from U.S. Census data together with urban tree cover percentage estimates for each state and the
 16 District of Columbia from remote sensing data, an approach consistent with Nowak et al. (2013).

17 This approach is also consistent with the default IPCC Gain-Loss methodology in IPCC (2006), although sufficient
 18 field data are not yet available to separately determine interannual gains and losses in C stocks in the living biomass
 19 of urban trees. Instead, the methodology applied here uses estimates of net C sequestration based on modeled
 20 estimates of decomposition, as given by Nowak et al. (2013).

21 The first step in the methodology is to estimate C in urban tree biomass. To develop urban tree carbon estimates
 22 Nowak et al. (2013) and previously published research (Nowak and Crane 2002; and Nowak 1994, 2007b, and
 23 2009) collected field measurements in a number of U.S. cities between 1989 and 2012. For a random sample of trees
 24 in representative cities, tree data were collected regarding stem diameter, tree height, crown height and crown width,
 25 tree location, species, and canopy condition. The data for each tree were converted into total dry-weight biomass
 26 estimates using allometric equations, a root-to-shoot ratio to convert aboveground biomass estimates to whole tree
 27 biomass, and wood moisture content. Total dry weight biomass was converted to C by dividing by two (50 percent
 28 carbon content). An adjustment factor of 0.8 was used for open grown trees to account for urban trees having less
 29 aboveground biomass for a given stem diameter than predicted by allometric equations based on forest trees (Nowak
 30 1994). Carbon storage estimates for deciduous trees include only C stored in wood. Estimated C storage was divided
 31 by tree cover in the area to estimate carbon storage per square meter of tree cover. The second step in the
 32 methodology is to estimate rates of tree growth for urban trees in the United States. In the Nowak et al. (2013)
 33 methodology that is applied here, growth rates were standardized for open-grown trees in areas with 153 days of
 34 frost free length based on measured data on tree growth. These growth rates were then adjusted to local tree
 35 conditions based on length of frost free season, crown competition (as crown competition increased, growth rates
 36 decreased), and tree condition (as tree condition decreased, growth rates decreased). For each tree, the difference in
 37 C storage estimates between year 1 and year (x + 1) represents the gross amount of C sequestered. These annual
 38 gross C sequestration rates for each tree were then scaled up to city estimates using tree population information. The

1 area of assessment for each city or state was defined by its political boundaries; parks and other forested urban areas
2 were thus included in sequestration estimates (Nowak 2011).

3 Most of the field data used to develop the methodology of Nowak et al. (2013) were analyzed using the U.S. Forest
4 Service's i-Tree Eco model (formerly Urban Forest Effects (UFORE) model). The i-Tree Eco computer model uses
5 standardized field data from randomly located plots, along with local hourly air pollution and meteorological data to
6 quantify urban forest structure, values of the urban forest, and environmental effects, including total C stored and
7 annual C sequestration. The model was used with field data from randomly sampled plots in each city or urban areas
8 in states to quantify the characteristics of the urban forest (Nowak et al. 2013).

9 Where gross C sequestration accounts for all carbon sequestered, net C sequestration for urban trees takes into
10 account C emissions associated with tree death and removals. In the third step in the methodology developed by
11 Nowak et al. (2002; 2013), estimates of net C emissions from urban trees were derived by applying estimates of
12 annual mortality based on tree condition, and assumptions about whether dead trees were removed from the site.
13 Estimates of annual mortality rates by diameter class and condition class were derived from a study of street-tree
14 mortality (Nowak 1986). Different decomposition rates were applied to dead trees left standing compared with those
15 removed from the site. For removed trees, different rates were applied to the removed/aboveground biomass in
16 contrast to the belowground biomass. The estimated annual gross C emission rates for each plot were then scaled up
17 to city estimates using tree population information.

18 The data for all 50 states and the District of Columbia are described in Nowak et al. (2013) and reproduced in Table
19 6-75, which builds upon previous research, including: Nowak and Crane (2002), Nowak et al. (2007), Nowak and
20 Greenfield (2012), and references cited therein. The full methodology development is described in the underlying
21 literature, and key details and assumptions were made as follows. The allometric equations applied to the field data
22 for the Nowak methodology for each tree were taken from the scientific literature (see Nowak 1994, Nowak et al.
23 2002), but if no allometric equation could be found for the particular species, the average result for the genus or
24 botanical relative was used. The adjustment (0.8) to account for less live tree biomass in open-grown urban trees
25 was based on information in Nowak (1994). Measured tree growth rates for street (Frelich 1992; Fleming 1988;
26 Nowak 1994), park (deVries 1987), and forest (Smith and Shifley 1984) trees were standardized to an average
27 length of growing season (153 frost free days) and adjusted for site competition and tree condition. Standardized
28 growth rates of trees of the same species or genus were then compared to determine the average difference between
29 standardized street tree growth and standardized park and forest growth rates. Crown light exposure (CLE)
30 measurements (number of sides and/or top of tree exposed to sunlight) were used to represent forest, park, and open
31 (street) tree growth conditions. Local tree base growth rates (BG) were then calculated as the average standardized
32 growth rate for open-grown trees multiplied by the number of frost free days divided by 153. Growth rates were then
33 adjusted for CLE. The CLE adjusted growth rate was then adjusted based on tree health and tree condition to
34 determine the final growth rate. Assumptions for which dead trees would be removed versus left standing were
35 developed specific to each land use and were based on expert judgment of the authors. Decomposition rates were
36 based on literature estimates (Nowak et al. 2013).

37 Estimates of gross and net sequestration rates for each of the 50 states and the District of Columbia (Table 6-75)
38 were compiled in units of C sequestration per unit area of tree canopy cover. These rates were used in conjunction
39 with estimates of state urban area and urban tree cover data (Nowak and Greenfield 2012) to calculate each state's
40 annual net C sequestration by urban trees. This method was described in Nowak et al. (2013) and has been modified
41 here to incorporate U.S. Census data.

42 Specifically, urban area estimates were based on 1990, 2000, and 2010 U.S. Census data. The 1990 U.S. Census
43 defined urban land as "urbanized areas," which included land with a population density greater than 1,000 people
44 per square mile, and adjacent "urban places," which had predefined political boundaries and a population total
45 greater than 2,500. In 2000, the U.S. Census replaced the "urban places" category with a new category of urban land
46 called an "urban cluster," which included areas with more than 500 people per square mile. In 2010, the Census
47 updated its definitions to have "urban areas" encompassing Census tract delineated cities with 50,000 or more
48 people, and "urban clusters" containing Census tract delineated locations with between 2,500 and 50,000 people.
49 Urban land area increased by approximately 23 percent from 1990 to 2000 and 14 percent from 2000 to 2010;
50 Nowak et al. (2005) estimate that the changes in the definition of urban land are responsible for approximately 20
51 percent of the total reported increase in urban land area from 1990 to 2000. Under all Census (i.e., 1990, 2000, and
52 2010) definitions, the urban category encompasses most cities, towns, and villages (i.e., it includes both urban and
53 suburban areas). *Settlements* area, as assessed in the Representation of the U.S. Land Base developed for this report,

1 encompassed all developed parcels greater than 0.1 hectares in size, including rural transportation corridors, and as
 2 previously mentioned represents a larger area than the Census-derived urban area estimates. However, the smaller,
 3 Census-derived urban area estimates were deemed to be more suitable for estimating national urban tree cover given
 4 the data available in the peer-reviewed literature (i.e., the data set available is consistent with Census urban rather
 5 than *Settlements* areas), and the recognized overlap in the changes in C stocks between urban forest and non-urban
 6 forest (see Planned Improvements below). U.S. Census urban area data is reported as a series of continuous blocks
 7 of urban area in each state. The blocks or urban area were summed to create each state's urban area estimate.

8 Net annual C sequestration estimates were derived for all 50 states and the District of Columbia by multiplying the
 9 gross annual emission estimates by 0.74, the standard ratio for net/gross sequestration set out in Table 3 of Nowak et
 10 al. (2013) (unless data existed for both gross and net sequestration for the state in Table 2 of Nowak et. al. (2013), in
 11 which case they were divided to get a state-specific ratio). The gross and net annual C sequestration values for each
 12 state were multiplied by each state's area of tree cover, which was the product of the state's urban/community area
 13 as defined in the U.S. Census (2012) and the state's urban/community tree cover percentage. The urban/community
 14 tree cover percentage estimates for all 50 states were obtained from Nowak and Greenfield (2012). The
 15 urban/community tree cover percentage estimate for the District of Columbia was obtained from Nowak et al.
 16 (2013). The urban area estimates were taken from the 2010 U.S. Census (2012). The equation, used to calculate the
 17 summed carbon sequestration amounts, can be written as follows:

$$\text{Net annual C sequestration} = \text{Gross sequestration rate} \times \text{Net to Gross sequestration ratio} \times \text{Urban Area} \times \text{\% Tree Cover}$$

18
19
20 **Table 6-75: Annual C Sequestration (Metric Tons C/Year), Tree Cover (Percent), and Annual**

1 Uncertainty and Time-Series Consistency

2 Uncertainty associated with changes in C stocks in urban trees includes the uncertainty associated with urban area,
3 percent urban tree coverage, and estimates of gross and net C sequestration for each of the 50 states and the District
4 of Columbia. A 10 percent uncertainty was associated with urban area estimates based on expert judgment.
5 Uncertainty associated with estimates of percent urban tree coverage for each of the 50 states was based on standard
6 error estimates reported by Nowak and Greenfield (2012). Uncertainty associated with estimate of percent urban tree
7 coverage for the District of Columbia was based on the standard error estimate reported by Nowak et al. (2013).
8 Uncertainty associated with estimates of gross and net C sequestration for each of the 50 states and the District of
9 Columbia was based on standard error estimates for each of the state-level sequestration estimates reported by
10 Nowak et al. (2013). These estimates are based on field data collected in each of the 50 states and the District of
11 Columbia, and uncertainty in these estimates increases as they are scaled up to the national level.

12 Additional uncertainty is associated with the biomass equations, conversion factors, and decomposition assumptions
13 used to calculate C sequestration and emission estimates (Nowak et al. 2002). These results also exclude changes in
14 soil C stocks, and there is some overlap between the urban tree C estimates and the forest tree C estimates as
15 detailed in Nowak et al. (2013). Due to data limitations, urban soil flux is not quantified as part of this analysis,
16 while reconciliation of urban tree and forest tree estimates will be addressed through the land-representation effort
17 described in the Planned Improvements section of this chapter.

18 A Monte Carlo (Approach 2) uncertainty analysis was applied to estimate the overall uncertainty of the
19 sequestration estimate. The results of the Approach 2 quantitative uncertainty analysis are summarized in Table
20 6-76. The net C flux from changes in C stocks in urban trees in 2015 was estimated to be between -135.3 and -47.3
21 MMT CO₂ Eq. at a 95 percent confidence level. This indicates a range of 47 percent more sequestration to 48
22 percent less sequestration than the 2015 flux estimate of -91.7 MMT CO₂ Eq.

23 **Table 6-76: Approach 2 Quantitative Uncertainty Estimates for Net C Flux from Changes in C**
24 **Stocks in Urban Trees (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Flux Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Flux Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Changes in C Stocks in Urban Trees	CO ₂	(91.7)	(135.3)	(47.3)	-47%	48%

Note: Parentheses indicate negative values or net sequestration.

^a Range of flux estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

1 Methodological recalculations were applied to the entire time series to ensure time-series consistency from 1990
2 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
3 above.

4 **QA/QC and Verification**

5 Tier 1 and Tier 2 QA/QC activities were conducted consistent with the U.S. QA/QC plan. Source-specific quality
6 control measures for urban trees included checking input data, documentation, and calculations to ensure data were
7 properly handled through the inventory process. Errors that were found during this process were corrected as
8 necessary.

9 **Planned Improvements**

10 A consistent representation of the managed land base in the United States is discussed in Section 6.1 Representation
11 of the U.S. Land Base, and discusses a planned improvement by the USDA Forest Service to reconcile the overlap
12 between urban forest and non-urban forest greenhouse gas inventories. Because some plots defined as “forest” in the
13 Forest Inventory and Analysis (FIA) program of the USDA Forest Service actually fall within the boundaries of the
14 areas also defined as Census urban, there may be “double-counting” of these land areas in estimates of C stocks and
15 fluxes for this report. Specifically, Nowak et al. (2013) estimates that 1.5 percent of forest plots measured by the
16 FIA program fall within land designated as Census urban, suggesting that approximately 1.5 percent of the C
17 reported in the Forest source category might also be counted in the Urban Trees source category.

18 Future research may also enable more complete coverage of changes in the C stock in urban trees for all *Settlements*
19 land. To provide estimates for all *Settlements*, research would need to establish the extent of overlap between the
20 areas of land included in the *Settlements* land use category and Census-defined urban areas, and would have to
21 separately characterize sequestration on non-urban *Settlements* land.

22 To provide more accurate emissions estimates in the urban forest greenhouse gas inventories, the following actions
23 will be taken:

- 24 a) Development of a national definition of “settlements”. Settlements are defined as including “all developed
25 land, including transportation infrastructure and human settlements of any size, unless they are already
26 included under other categories. This should be consistent with the selection of national definitions”. In the
27 U.S., different types of classifications can be used to determine settlements e.g., Census urban, Census
28 urban/community, National Land Cover Dataset, and National Resources Inventory. A combination of
29 these data will be used to encompass settlement areas and improve consistency with the *Representation of*
30 *the U.S Land Base* chapter;
- 31 b) For settlement areas, estimates of land area will be obtained for 1990, 2000 and 2010 and projections
32 developed for annual growth during the 2010 to 2020 period;
- 33 c) 2,500 random points will be laid on aerial images using Google Earth imagery to estimate tree cover in the
34 settlement areas circa 1990, 2000 and 2010. Trends in tree cover change will be used to estimate tree cover
35 in settlement between 2010 and 2020;
- 36 d) Photo interpretation of settlement tree cover will be updated bi-annually to update tree cover estimates and
37 trends;
- 38 e) A review of recent literature will be performed to update C storage, sequestration and net-to-gross
39 sequestration rates per unit tree cover.
- 40 f) C rates per unit tree cover will be applied to tree cover estimates within estimated settlement areas annually
41 to estimate past and current C values.
- 42 g) Settlement areas will updated approximately every 10 years based on updated data from the US Census and
43 NLCD developed land.

44 **N₂O Fluxes from Settlement Soils (IPCC Source Category 4E1)**

45 Of the synthetic N fertilizers applied to soils in the United States, approximately 3.1 percent are currently applied to
46 lawns, golf courses, and other landscaping occurring within settlement areas. Application rates are lower than those
47 occurring on cropped soils, and, therefore, account for a smaller proportion of total U.S. soil N₂O emissions per unit
48 area. In addition to synthetic N fertilizers, a portion of surface applied sewage sludge is applied to settlement areas,

1 and drained organic soils (i.e., soils with high organic matter content, known as *Histosols*) also contribute to
 2 emissions of soil N₂O.

3 N additions to soils result in direct and indirect N₂O emissions. Direct emissions occur on-site due to the N
 4 additions. Indirect emissions result from fertilizer and sludge N that is transformed and transported to another
 5 location in a form other than N₂O (ammonia [NH₃] and nitrogen oxide [NO_x] volatilization, nitrate [NO₃⁻] leaching
 6 and runoff), and later converted into N₂O at the off-site location. The indirect emissions are assigned to settlements
 7 because the management activity leading to the emissions occurred in settlements.

8 Total N₂O emissions from *Settlements Remaining Settlements*⁷⁴ are 2.6 MMT CO₂ Eq. (9 kt of N₂O) in 2015. There
 9 is an overall increase of 81 percent from 1990 to 2015 due to an expanding settlement area leading to more synthetic
 10 N fertilizer applications. Interannual variability in these emissions is directly attributable to interannual variability in
 11 total synthetic fertilizer consumption, area of drained organic soils, and sewage sludge applications in the United
 12 States. Emissions from this source are summarized in Table 6-77.

13 **Table 6-77: N₂O Fluxes from Soils in *Settlements Remaining Settlements* (MMT CO₂ Eq. and
 14 kt N₂O)**

Note: Totals may not sum due to independent rounding.

Estimates of Soil N₂O for *Settlements Remaining Settlements* include emissions from *Land Converted to Settlements* because it was not possible to separate the activity data.

15 Methodology

16 For settlement soils, the IPCC Tier 1 approach is used to estimate soil N₂O emissions from synthetic N fertilizer,
 17 sewage sludge additions, and drained organic soils. Estimates of direct N₂O emissions from soils in settlements are
 18 based on the amount of N in synthetic commercial fertilizers applied to settlement soils, the amount of N in sewage
 19 sludge applied to non-agricultural land and surface disposal (see Annex 3.12 for a detailed discussion of the
 20 methodology for estimating sewage sludge application), and the area of drained organic soils used for settlements.

21 Nitrogen applications to settlement soils are estimated using data compiled by the USGS (Ruddy et al. 2006). The
 22 USGS estimated on-farm and non-farm fertilizer use is based on sales records at the county level from 1982 through
 23 2001 (Ruddy et al. 2006). Non-farm N fertilizer is assumed to be applied to settlements and forest lands; values for
 24 2002 through 2015 are based on 2001 values adjusted for annual total N fertilizer sales in the United States because
 25 there is no new activity data on application after 2001. Settlement application is calculated by subtracting forest

⁷⁴ Estimates of Soil N₂O for *Settlements Remaining Settlements* include emissions from *Land Converted to Settlements* because it was not possible to separate the activity data.

1 application from total non-farm fertilizer use. Sewage sludge applications are derived from national data on sewage
 2 sludge generation, disposition, and N content (see Annex 3.12 for further detail). The total amount of N resulting
 3 from these sources is multiplied by the IPCC default emission factor for applied N (one percent) to estimate direct
 4 N₂O emissions (IPCC 2006). The IPCC (2006) Tier 1 method is used to estimate direct N₂O emissions due to
 5 drainage of organic soils in settlements at the national scale. Estimates of the total area of drained organic soils are
 6 obtained from the 2012 NRI (USDA-NRCS 2015) using soils data from the Soil Survey Geographic Database
 7 (SSURGO) (Soil Survey Staff 2011). To estimate annual emissions, the total area is multiplied by the IPCC default
 8 emission factor for temperate regions (IPCC 2006). This Inventory does not include soil N₂O emissions from
 9 drainage of organic soils in Alaska and federal lands, although this is a planned improvement for a future Inventory.

10 For indirect emissions, the total N applied from fertilizer and sludge is multiplied by the IPCC default factors of 10
 11 percent for volatilization and 30 percent for leaching/runoff to calculate the amount of N volatilized and the amount
 12 of N leached/runoff. The amount of N volatilized is multiplied by the IPCC default factor of one percent for the
 13 portion of volatilized N that is converted to N₂O off-site and the amount of N leached/runoff is multiplied by the
 14 IPCC default factor of 0.075 percent for the portion of leached/runoff N that is converted to N₂O off-site. The
 15 resulting estimates are summed to obtain total indirect emissions.

16 **Uncertainty and Time-Series Consistency**

17 The amount of N₂O emitted from settlements depends not only on N inputs and fertilized area as well as drained
 18 organic soils, but also on a large number of variables, including organic C availability, oxygen gas partial pressure,
 19 soil moisture content, pH, temperature, and irrigation/watering practices. The effect of the combined interaction of
 20 these variables on N₂O flux is complex and highly uncertain. The IPCC default methodology does not explicitly
 21 incorporate any of these variables, except variations in fertilizer N and sewage sludge application rates. All
 22 settlement soils are treated equivalently under this methodology.

23 Uncertainties exist in both the fertilizer N and sewage sludge application rates in addition to the emission factors.
 24 Uncertainty in fertilizer N application is assigned a default level of ±50 percent.⁷⁵ Uncertainty in drained organic
 25 soils is based on the estimated variance from the NRI survey (USDA-NRCS 2015). Uncertainty in the amounts of
 26 sewage sludge applied to non-agricultural lands and used in surface disposal is derived from variability in several
 27 factors, including: (1) N content of sewage sludge; (2) total sludge applied in 2000; (3) wastewater existing flow in
 28 1996 and 2000; and (4) the sewage sludge disposal practice distributions to non-agricultural land application and
 29 surface disposal. In addition, the uncertainty ranges around 2005 activity data and emission factor input variables are
 30 directly applied to the 2015 emission estimates. Uncertainty in the direct and indirect emission factors is provided by
 31 IPCC (2006).

32 Uncertainty is quantified using simple error propagation methods (IPCC 2006), and the results are summarized in
 33 Table 6-78. Direct N₂O emissions from soils in *Settlements Remaining Settlements* in 2015 are estimated to be
 34 between 1.0 and 5.2 MMT CO₂ Eq. at a 95 percent confidence level. This indicates a range of 49 percent below to
 35 163 percent above the 2015 emission estimate of 2.0 MMT CO₂ Eq. Indirect N₂O emissions in 2015 are between 0.1
 36 and 1.9 MMT CO₂ Eq., ranging from a -85 percent to 212 percent around the estimate of 0.6 MMT CO₂ Eq.

37 **Table 6-78: Quantitative Uncertainty Estimates of N₂O Emissions from Soils in *Settlements***
 38 ***Remaining Settlements* (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emissions (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Settlements Remaining Settlements						
Direct N ₂ O Fluxes from Soils	N ₂ O	2.0	1.0	5.2	-49%	163%
Indirect N ₂ O Fluxes from Soils	N ₂ O	0.6	0.1	1.9	-85%	212%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.
 Note: These estimates include direct and indirect N₂O emissions from N fertilizer additions to both *Settlements Remaining Settlements* and from *Land Converted to Settlements*.

⁷⁵ No uncertainty is provided with the USGS fertilizer consumption data (Ruddy et al. 2006) so a conservative ±50 percent is used in the analysis.

1 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
2 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
3 above.

4 **QA/QC and Verification**

5 The spreadsheet containing fertilizer, drainage of organic soils, and sewage sludge applied to settlements and
6 calculations for N₂O and uncertainty ranges have been checked and verified.

7 **Recalculations Discussion**

8 Methodological recalculations in the current Inventory are associated with accounting for emissions from drained
9 organic soils in settlements, which were not included in previous inventories. The change resulted in a relatively
10 minor increase emissions on average across the time series by 0.13 MMT CO₂ Eq., which is an 8 percent increase in
11 the reported emissions compared to the previous Inventory.

12 **Planned Improvements**

13 This source will be extended to include soil N₂O emissions from drainage of organic soils in settlements of Alaska
14 and federal lands in order to provide a complete inventory of emissions for this category.

15 **Changes in Yard Trimming and Food Scrap Carbon Stocks in** 16 **Landfills**

17 In the United States, yard trimmings (i.e., grass clippings, leaves, and branches) and food scraps account for a
18 significant portion of the municipal waste stream, and a large fraction of the collected yard trimmings and food
19 scraps are put in landfills. Carbon (C) contained in landfilled yard trimmings and food scraps can be stored for very
20 long periods.

21 Carbon-storage estimates within the Inventory are associated with particular land uses. For example, harvested wood
22 products are reported under *Forest Land Remaining Forest Land* because these wood products originated from the
23 forest ecosystem. Similarly, C stock changes in yard trimmings and food scraps are reported under *Settlements*
24 *Remaining Settlements* because the bulk of the C, which comes from yard trimmings, originates from settlement
25 areas. While the majority of food scraps originate from cropland and grassland, this Inventory has chosen to report
26 these with the yard trimmings in the *Settlements Remaining Settlements* section. Additionally, landfills are
27 considered part of the managed land base under settlements (see Section 6.1 *Representation of the U.S. Land Base*),
28 and reporting these C stock changes that occur entirely within landfills fits most appropriately within the *Settlements*
29 *Remaining Settlements* section.

30 Both the amount of yard trimmings collected annually and the fraction that is landfilled have declined over the last
31 decade. In 1990, over 53 million metric tons (wet weight) of yard trimmings and food scraps were generated (i.e.,
32 put at the curb for collection to be taken to disposal sites or to composting facilities) (EPA 2016). Since then,
33 programs banning or discouraging yard trimmings disposal have led to an increase in backyard composting and the
34 use of mulching mowers, and a consequent 2.3 percent decrease in the tonnage of yard trimmings generated (i.e.,
35 collected for composting or disposal in landfills). At the same time, an increase in the number of municipal
36 composting facilities has reduced the proportion of collected yard trimmings that are discarded in landfills—from 72
37 percent in 1990 to 31 percent in 2015. The net effect of the reduction in generation and the increase in composting is
38 a 57 percent decrease in the quantity of yard trimmings disposed of in landfills since 1990.

39 Food scrap generation has grown by 61 percent since 1990, and while the proportion of total food scraps generated
40 that are eventually discarded in landfills has decreased slightly, from 82 percent in 1990 to 76 percent in 2015, the
41 tonnage disposed of in landfills has increased considerably (by 50 percent) due to the increase in food scrap
42 generation. Although the total tonnage of food scraps disposed of in landfills has increased from 1990 to 2015, the
43 difference in the amount of food scraps added from one year to the next generally decreased, and consequently the

annual carbon stock *net changes* from food scraps have generally decreased as well (as shown in Table 6-79 and Table 6-80). As described in the Methodology section, the carbon stocks are modeled using data on the amount of food scraps landfilled since 1960. These food scraps decompose over time, producing CH₄ and CO₂. Decomposition happens at a higher rate initially, then decreases. As decomposition decreases, the carbon stock becomes more stable. Because the cumulative carbon stock left in the landfill from previous years is (1) not decomposing as much as the carbon introduced from food scraps in a single more recent year; and (2) is much larger than the carbon introduced from food scraps in a single more recent year, the total carbon stock in the landfill is primarily driven by the more stable ‘older’ carbon stock, thus resulting in less annual change in later years.”

Overall, the decrease in the landfill disposal rate of yard trimmings has more than compensated for the increase in food scrap disposal in landfills, and the net result is a decrease in annual *net change* landfill C storage from 26.0 MMT CO₂ Eq. (7.1 MMT C) in 1990 to 11.8 MMT CO₂ Eq. (3.2 MMT C) in 2015 (Table 6-79 and Table 6-80).

Note: Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

Methodology

When wastes of biogenic origin (such as yard trimmings and food scraps) are landfilled and do not completely decompose, the C that remains is effectively removed from the C cycle. Empirical evidence indicates that yard trimmings and food scraps do not completely decompose in landfills (Barlaz 1998, 2005, 2008; De la Cruz and Barlaz 2010), and thus the stock of C in landfills can increase, with the net effect being a net atmospheric removal of C. Estimates of net C flux resulting from landfilled yard trimmings and food scraps were developed by estimating the change in landfilled C stocks between inventory years, based on methodologies presented for the *Land Use, Land-Use Change, and Forestry* sector in IPCC (2003) and the *2006 IPCC Guidelines for National Greenhouse Gas Inventories*. Carbon stock estimates were calculated by determining the mass of landfilled C resulting from yard trimmings and food scraps discarded in a given year; adding the accumulated landfilled C from previous years; and subtracting the mass of C that was landfilled in previous years and has since decomposed.

To determine the total landfilled C stocks for a given year, the following were estimated: (1) The composition of the yard trimmings; (2) the mass of yard trimmings and food scraps discarded in landfills; (3) the C storage factor of the landfilled yard trimmings and food scraps; and (4) the rate of decomposition of the degradable C. The composition of yard trimmings was assumed to be 30 percent grass clippings, 40 percent leaves, and 30 percent branches on a wet weight basis (Oshins and Block 2000). The yard trimmings were subdivided, because each component has its own unique adjusted C storage factor (i.e., moisture content and C content) and rate of decomposition. The mass of

1 yard trimmings and food scraps disposed of in landfills was estimated by multiplying the quantity of yard trimmings
2 and food scraps discarded by the proportion of discards managed in landfills. Data on discards (i.e., the amount
3 generated minus the amount diverted to centralized composting facilities) for both yard trimmings and food scraps
4 were taken primarily from *Advancing Sustainable Materials Management: Facts and Figures 2014* (EPA 2016),
5 which provides data for 1960, 1970, 1980, 1990, 2000, 2005, 2009 and 2011 through 2013. To provide data for
6 some of the missing years, detailed backup data were obtained from historical data tables that EPA developed for
7 1960 through 2013 (EPA 2015). Remaining years in the time series for which data were not provided were estimated
8 using linear interpolation. Data for 2015 are not yet available, so they were set equal to 2014 values. The EPA
9 (2016) report and historical data tables (EPA 2015) do not subdivide the discards (i.e., total generated minus
10 composted) of individual materials into masses landfilled and combusted, although it provides a mass of overall
11 waste stream discards managed in landfills⁷⁶ and combustors with energy recovery (i.e., ranging from 67 percent
12 and 33 percent, respectively, in 1960 to 92 percent and 8 percent, respectively, in 1985); it is assumed that the
13 proportion of each individual material (food scraps, grass, leaves, branches) that is landfilled is the same as the
14 proportion across the overall waste stream.

15 The amount of C disposed of in landfills each year, starting in 1960, was estimated by converting the discarded
16 landfilled yard trimmings and food scraps from a wet weight to a dry weight basis, and then multiplying by the
17 initial (i.e., pre-decomposition) C content (as a fraction of dry weight). The dry weight of landfilled material was
18 calculated using dry weight to wet weight ratios (Tchobanoglous et al. 1993, cited by Barlaz 1998) and the initial C
19 contents and the C storage factors were determined by Barlaz (1998, 2005, 2008) (Table 6-81).

20 The amount of C remaining in the landfill for each subsequent year was tracked based on a simple model of C fate.
21 As demonstrated by Barlaz (1998, 2005, 2008), a portion of the initial C resists decomposition and is essentially
22 persistent in the landfill environment. Barlaz (1998, 2005, 2008) conducted a series of experiments designed to
23 measure biodegradation of yard trimmings, food scraps, and other materials, in conditions designed to promote
24 decomposition (i.e., by providing ample moisture and nutrients). After measuring the initial C content, the materials
25 were placed in sealed containers along with methanogenic microbes from a landfill. Once decomposition was
26 complete, the yard trimmings and food scraps were re-analyzed for C content; the C remaining in the solid sample
27 can be expressed as a proportion of the initial C (shown in the row labeled “C Storage Factor, Proportion of Initial C
28 Stored (%)” in Table 6-81).

29 The modeling approach applied to simulate U.S. landfill C flows builds on the findings of Barlaz (1998, 2005,
30 2008). The proportion of C stored is assumed to persist in landfills. The remaining portion is assumed to degrade
31 over time, resulting in emissions of CH₄ and CO₂. (The CH₄ emissions resulting from decomposition of yard
32 trimmings and food scraps are accounted for in the *Waste* chapter.) The degradable portion of the C is assumed to
33 decay according to first-order kinetics. The decay rates for each of the materials are shown in Table 6-81.

34 The first-order decay rates, k , for each refuse type were derived from De la Cruz and Barlaz (2010). De la Cruz and
35 Barlaz (2010) calculate first-order decay rates using laboratory data published in Eleazer et al. (1997), and a
36 correction factor, f , is calculated so that the weighted average decay rate for all components is equal to the EPA AP-
37 42 default decay rate (0.04) for mixed MSW for regions that receive more than 25 inches of rain annually (EPA
38 1995). Because AP-42 values were developed using landfill data from approximately 1990, 1990 waste composition
39 for the United States from EPA’s *Characterization of Municipal Solid Waste in the United States: 1990 Update* was
40 used to calculate f . This correction factor is then multiplied by the Eleazer et al. (1997) decay rates of each waste
41 component to develop field-scale first-order decay rates.

42 De la Cruz and Barlaz (2010) also use other assumed initial decay rates for mixed MSW in place of the AP-42
43 default value based on different types of environments in which landfills in the United States are located, including
44 dry conditions (less than 25 inches of rain annually, $k=0.02$) and bioreactor landfill conditions (moisture is
45 controlled for rapid decomposition, $k=0.12$). As in the Landfills section of the Inventory (Section 7.1), which
46 estimates CH₄ emissions, the overall MSW decay rate is estimated by partitioning the U.S. landfill population into
47 three categories based on annual precipitation ranges of: (1) Less than 20 inches of rain per year, (2) 20 to 40 inches

⁷⁶ EPA (2016 and 2015) reports discards in two categories: “combustion with energy recovery” and “landfill, other disposal,” which includes combustion without energy recovery. For years in which there is data from previous EPA reports on combustion without energy recovery, EPA assumes these estimates are still applicable. For 2000 to present, EPA assumes that any combustion of MSW that occurs includes energy recovery, so all discards to “landfill, other disposal” are assumed to go to landfills.

1 of rain per year, and (3) greater than 40 inches of rain per year. These correspond to overall MSW decay rates of
 2 0.020, 0.038, and 0.057 year⁻¹, respectively.

3 De la Cruz and Barlaz (2010) calculate component-specific decay rates corresponding to the first value (0.020
 4 year⁻¹), but not for the other two overall MSW decay rates. To maintain consistency between landfill methodologies
 5 across the Inventory, the correction factors (*f*) were developed for decay rates of 0.038 and 0.057 year⁻¹ through
 6 linear interpolation. A weighted national average component-specific decay rate was calculated by assuming that
 7 waste generation is proportional to population (the same assumption used in the landfill methane emission estimate),
 8 based on population data from the 2000 U.S. Census. The component-specific decay rates are shown in Table 6-81.

9 For each of the four materials (grass, leaves, branches, food scraps), the stock of C in landfills for any given year is
 10 calculated according to Equation 1:

$$11 \quad LFC_{i,t} = \sum_n^t W_{i,n} \times (1 - MC_i) \times ICC_i \times \{ [CS_i \times ICC_i] + [(1 - (CS_i \times ICC_i)) \times e^{-k(t-n)}] \}$$

14 where,

- 15 *t* = Year for which C stocks are being estimated (year),
- 16 *i* = Waste type for which C stocks are being estimated (grass, leaves, branches, food scraps),
- 17 *LFC_{i,t}* = Stock of C in landfills in year *t*, for waste *i* (metric tons),
- 18 *W_{i,n}* = Mass of waste *i* disposed of in landfills in year *n* (metric tons, wet weight),
- 19 *n* = Year in which the waste was disposed of (year, where 1960 < *n* < *t*),
- 20 *MC_i* = Moisture content of waste *i* (percent of water),
- 21 *CS_i* = Proportion of initial C that is stored for waste *i* (percent),
- 22 *ICC_i* = Initial C content of waste *i* (percent),
- 23 *e* = Natural logarithm, and
- 24 *k* = First-order decay rate for waste *i*, (year⁻¹).

25 For a given year *t*, the total stock of C in landfills (*TLFC_t*) is the sum of stocks across all four materials (grass,
 26 leaves, branches, food scraps). The annual flux of C in landfills (*F_t*) for year *t* is calculated in Equation 2 as the
 27 change in stock compared to the preceding year:

$$28 \quad F_t = TLFC_t - TLFC_{(t-1)}$$

29 Thus, as seen in Equation 1, the C placed in a landfill in year *n* is tracked for each year *t* through the end of the
 30 inventory period (2015). For example, disposal of food scraps in 1960 resulted in depositing about 1,135,000 metric
 31 tons of C in landfills. Of this amount, 16 percent (179,000 metric tons) is persistent; the remaining 84 percent
 32 (956,000 metric tons) is degradable. By 1965, more than half of the degradable portion (518,000 metric tons)
 33 decomposes, leaving a total of 617,000 metric tons (the persistent portion, plus the remainder of the degradable
 34 portion).

35 Continuing the example, by 2015, the total food scraps C originally disposed of in 1960 had declined to 179,000
 36 metric tons (i.e., virtually all degradable C had decomposed). By summing the C remaining from 1960 with the C
 37 remaining from food scraps disposed of in subsequent years (1961 through 2015), the total landfill C from food
 38 scraps in 2015 was 42.6 million metric tons. This value is then added to the C stock from grass, leaves, and branches
 39 to calculate the total landfill C stock in 2015, yielding a value of 268.0 million metric tons (as shown in Table 6-82).
 40 In the same way total net flux is calculated for forest C and harvested wood products, the total net flux of landfill C
 41 for yard trimmings and food scraps for a given year (Table 6-80) is the difference in the landfill C stock for that year
 42 and the stock in the preceding year. For example, the net change in 2015 shown in Table 6-80 (3.2 MMT C) is equal
 43 to the stock in 2015 (268.0 MMT C) minus the stock in 2014 (264.8 MMT C).

44 The C stocks calculated through this procedure are shown in Table 6-82.

45 **Table 6-81: Moisture Contents, C Storage Factors (Proportions of Initial C Sequestered),**
 46 **Initial C Contents, and Decay Rates for Yard Trimmings and Food Scraps in Landfills**

Variable	Yard Trimmings			Food Scraps
	Grass	Leaves	Branches	
Moisture Content (% H ₂ O)	70	30	10	70

C Storage Factor, Proportion of Initial C Stored (%)	53	85	77	16
Initial C Content (%)	45	46	49	51
Decay Rate (year ⁻¹)	0.323	0.185	0.016	0.156

1 **Table 6-82: C Stocks in Yard Trimmings and Food Scraps in Landfills (MMT C)**

Carbon Pool	1990	2005	2011	2012	2013	2014	2015
Yard Trimmings	155.8	202.9	216.1	218.6	220.9	223.1	225.4
Branches	14.5	18.1	19.3	19.5	19.7	19.9	20.2
Leaves	66.7	87.3	93.4	94.5	95.5	96.6	97.6
Grass	74.6	97.5	103.4	104.5	105.6	106.6	107.6
Food Scraps	17.6	32.8	38.9	39.8	40.7	41.6	42.6
Total Carbon Stocks	173.5	235.6	255.0	258.3	261.5	264.8	268.0

Note: Totals may not sum due to independent rounding.

2 Uncertainty and Time-Series Consistency

3 The uncertainty analysis for landfilled yard trimmings and food scraps includes an evaluation of the effects of
4 uncertainty for the following data and factors: disposal in landfills per year (tons of C), initial C content, moisture
5 content, decay rate, and proportion of C stored. The C storage landfill estimates are also a function of the
6 composition of the yard trimmings (i.e., the proportions of grass, leaves and branches in the yard trimmings
7 mixture). There are respective uncertainties associated with each of these factors.

8 A Monte Carlo (Approach 2) uncertainty analysis was applied to estimate the overall uncertainty of the
9 sequestration estimate. The results of the Approach 2 quantitative uncertainty analysis are summarized in Table
10 6-83. Total yard trimmings and food scraps CO₂ flux in 2015 was estimated to be between -18.3 and -4.6 MMT CO₂
11 Eq. at a 95 percent confidence level (or 19 of 20 Monte Carlo stochastic simulations). This indicates a range of 56
12 percent below to 61 percent above the 2015 flux estimate of -11.8 MMT CO₂ Eq.

13 **Table 6-83: Approach 2 Quantitative Uncertainty Estimates for CO₂ Flux from Yard**
14 **Trimmings and Food Scraps in Landfills (MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Flux		Uncertainty Range Relative to Flux Estimate ^a			
		Estimate (MMT CO ₂ Eq.)	Relative to Flux Estimate ^a				
			Lower Bound	Upper Bound	Lower Bound	Upper Bound	
Yard Trimmings and Food Scraps	CO ₂	(11.8)	(18.3)	(4.6)	-56%	61%	

^a Range of flux estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Note: Parentheses indicate negative values or net C sequestration.

15 Methodological recalculations were applied to the entire time series to ensure time-series consistency from 1990
16 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
17 above.

18 QA/QC and Verification

19 Tier 1 and Tier 2 QA/QC activities were conducted consistent with the U.S. QA/QC plan. Source-specific quality
20 control measures for *Landfilled Yard Trimming and Food Scraps* included checking that input data were properly
21 transposed within the spreadsheet, checking calculations were correct, and confirming that all activity data and
22 calculations documentation was complete and updated to ensure data were properly handled through the inventory
23 process.

24 Order of magnitude checks and checks of time-series consistency were performed to ensure data were updated
25 correctly and any changes in emissions estimates were reasonable and reflected changes in activity data. An annual

1 change trend analysis was also conducted to ensure the validity of the emissions estimates. Errors that were found
2 during this process were corrected as necessary.

3 **Recalculations Discussion**

4 As noted in the Methodology section, activity data for this category are obtained from the *Advancing Sustainable*
5 *Materials Management: Facts and Figures* report. The current Inventory has been revised to reflect updated data in
6 the most recent report. The recalculations based on these updates resulted in the following changes for this category:
7 a 0.3 percent decrease in sequestration in 2012, a 0.6 decrease in sequestration in 2013, and a 3.1 percent increase in
8 sequestration in 2014.

9 **Planned Improvements**

10 Future work is planned to evaluate the consistency between the estimates of C storage described in this chapter and
11 the estimates of landfill CH₄ emissions described in the Waste chapter. For example, the Waste chapter does not
12 distinguish landfill CH₄ emissions from yard trimmings and food scraps separately from landfill CH₄ emissions from
13 total bulk (i.e., municipal solid) waste, which includes yard trimmings and food scraps.

14 In addition, EPA will evaluate additional data from recent peer-reviewed literature that may modify the default C
15 storage factors, initial C contents, and decay rates for yard trimmings and food scraps in landfills. Based upon this
16 evaluation, changes may be made to the default values. EPA will also investigate updating the weighted national
17 average component-specific decay rate using new U.S. Census data, if any are available.

18 EPA will also evaluate the yard waste composition to determine if changes need to be made based on changes in
19 residential practices, EPA will conduct a review of available literature to determine if there are changes in the
20 allocation of yard trimmings. For example, leaving grass clippings in place is becoming a more common practice,
21 thus reducing the percentage of grass clippings in yard trimmings disposed in landfills.

22 **6.11 Land Converted to Settlements (IPCC** 23 **Source Category 3B5b)**

24 *Land Converted to Settlements* includes all settlements in an Inventory year that had been in another land use(s)
25 during the previous 20 years (USDA-NRCS 2015).⁷⁷ For example, cropland, grassland or forest land converted to
26 settlements during the past 20 years would be reported in this category. Recently-converted lands are retained in this
27 category for 20 years as recommended by IPCC (2006). This Inventory includes all settlements in the conterminous
28 U.S. and Hawaii, but does not include settlements in Alaska. Areas of drained organic soils on settlements in federal
29 lands are also not included in this Inventory. Consequently, there is a discrepancy between the total amount of
30 managed area for *Land Converted to Settlements* (see Section 0—Representation of the U.S. Land Base) and the
31 settlements area included in the inventory analysis.

32 Land use change can lead to large losses of carbon (C) to the atmosphere, particularly conversions from forest land
33 (Houghton et al. 1983). Moreover, conversion of forest to another land use (i.e., deforestation) is one of the largest
34 anthropogenic sources of emissions to the atmosphere globally (Schimel 1995), although this source may be
35 declining according to a recent assessment (Tubiello et al. 2015).

36 IPCC (2006) recommends reporting changes in biomass, dead organic matter, and soil organic C (SOC) stocks due
37 to land use change.⁷⁸ All soil C stock changes are estimated and reported for *Land Converted to Settlements*, but

⁷⁷ NRI survey locations are classified according to land-use histories starting in 1979, and consequently the classifications are based on less than 20 years from 1990 to 2001. This may have led to an underestimation of *Land Converted to Settlements* in the early part of the time series to the extent that some areas are converted to settlements from 1971 to 1978.

⁷⁸ CO₂ emissions associated with liming and urea fertilization are also estimated but included in the Agriculture chapter of the report.

1 there is limited reporting of other pools in this Inventory. Loss of aboveground and belowground biomass, dead
 2 wood and litter C are reported for *Forest Land Converted to Settlements*, but not for other land use conversions to
 3 settlements.

4 *Forest Land Converted to Settlements* from 1990 to 2015 led to losses of aboveground and belowground biomass,
 5 dead wood and litter C losses that averaged 89.0, 18.2, 15.6, and 15.6 MMT CO₂ Eq. per year (24.3, 5.0, 4.3, and 4.2
 6 MMT C per year). Mineral and organic soils also lost an average of 20.2 and 2.0 MMT CO₂ Eq. per year (5.5 and
 7 0.6 MMT C per year) between 1990 and 2015. The total net flux is 150.2 MMT CO₂ Eq. in 2015, which is a 21
 8 percent increase in CO₂ emissions compared to the emissions in the initial reporting year of 1990.

Notes: Totals may not sum due to independent rounding. Estimates after 2012 for mineral and organic soils are based on NRI data from 2012 and therefore may not fully reflect changes occurring in the latter part of the time series.

1 Methodology

2 The following section includes a description of the methodology used to estimate C stock changes for *Land*
3 *Converted to Settlements*, including (1) loss of aboveground and belowground biomass, dead wood and litter C with
4 conversion of forest lands to settlements, as well as (2) the impact of land use conversions to settlements on mineral
5 and organic soils.

6 Biomass, Dead Biomass, and Litter Carbon Stock Changes

7 A Tier 2 method is applied to estimate aboveground biomass C stock changes for *Forest Land Converted to*
8 *Settlements*. For this method, forest land conversions to settlements were identified in each state and C density
9 estimates were compiled by state for aboveground biomass, belowground biomass, dead wood, and litter for
10 settlements (assumed to be zero since no reference biomass C density estimates exist) and forest land use categories.
11 The difference between the stocks is reported as the stock change under the assumption that the change occurred in
12 the year of the conversion. Reference C density estimates (i.e., aboveground biomass, belowground biomass, dead
13 wood, and litter) for forest lands have been estimated from data in the Forest Inventory and Analysis (FIA) program
14 within the USDA Forest Service (USDA Forest Service 2015). If FIA plots include data on individual trees,
15 aboveground and belowground C density estimates are based on Woodall et al. (2011). Aboveground and
16 belowground biomass estimates also include live understory which is a minor component of biomass defined as all
17 biomass of undergrowth plants in a forest, including woody shrubs and trees less than 2.54 cm dbh. For this
18 Inventory, it was assumed that 10 percent of total understory C mass is belowground (Smith et al. 2006). Estimates
19 of C density are based on information in Birdsey (1996) and biomass estimates from Jenkins et al. (2003). If FIA
20 plots include data on standing dead trees, standing dead tree C density is estimated following the basic method
21 applied to live trees (Woodall et al. 2011) with additional modifications to account for decay and structural loss
22 (Domke et al. 2011; Harmon et al. 2011). If FIA plots include data on downed dead wood, downed dead wood C
23 density is estimated based on measurements of a subset of FIA plots for downed dead wood (Domke et al. 2013;

1 Woodall and Monleon 2008). Downed dead wood is defined as pieces of dead wood greater than 7.5 cm diameter, at
2 transect intersection, that are not attached to live or standing dead trees. This includes stumps and roots of harvested
3 trees. To facilitate the downscaling of downed dead wood C estimates from the state-wide population estimates to
4 individual plots, downed dead wood models specific to regions and forest types within each region are used. Litter C
5 is the pool of organic C (also known as duff, humus, and fine woody debris) above the mineral soil and includes
6 woody fragments with diameters of up to 7.5 cm. A subset of FIA plots are measured for litter C. If FIA plots
7 include litter material, a modeling approach using litter C measurements from FIA plots is used to estimate litter C
8 density (Domke et al. 2016). See Annex 3.13 for more information about reference C density estimates for forest
9 land.

10 **Soil Carbon Stock Changes**

11 Soil C stock changes are estimated for *Land Converted to Settlements* according to land-use histories recorded in the
12 2012 USDA NRI survey for non-federal lands (USDA-NRCS 2015). Land use and some management information
13 were originally collected for each NRI survey locations on a 5-year cycle beginning in 1982. In 1998, the NRI
14 program began collecting annual data, and the annual data are currently available through 2012 (USDA-NRCS
15 2015). However, this Inventory only uses NRI data through 2012 because newer data were not available. NRI
16 survey locations are classified as *Land Converted to Settlements* in a given year between 1990 and 2012 if the land
17 use is settlements but had been classified as another use during the previous 20 years. NRI survey locations are
18 classified according to land-use histories starting in 1979, and consequently the classifications are based on less than
19 20 years from 1990 to 1998. This may have led to an underestimation of *Land Converted to Settlements* in the early
20 part of the time series to the extent that some areas are converted to grassland between 1971 and 1978. For federal
21 lands, the land use history is derived from land cover changes in the National Land Cover Dataset (Homer et al.
22 2007; Fry et al. 2011; Homer et al. 2015).

23 *Mineral Soil Carbon Stock Changes*

24 An IPCC Tier 2 method (Ogle et al. 2003) is applied to estimate C stock changes for *Land Converted to Settlements*
25 on mineral soils. Data on climate, soil types, land-use, and land management activity are used to classify land area
26 and apply appropriate stock change factors (Ogle et al. 2003, 2006). Reference C stocks are estimated using the
27 National Soil Survey Characterization Database (NRCS 1997) with cultivated cropland as the reference condition,
28 rather than native vegetation as used in IPCC (2006). Soil measurements under agricultural management are much
29 more common and easily identified in the National Soil Survey Characterization Database (NRCS 1997) than are
30 soils under a native condition, and therefore cultivated cropland provide a more robust sample for estimating the
31 reference condition. United States-specific C stock change factors are derived from published literature to determine
32 the impact of management practices on SOC storage (Ogle et al. 2003, Ogle et al. 2006). However, there are
33 insufficient data to estimate a set of land use, management, and input factors for settlements. Moreover, the 2012
34 NRI survey data (USDA-NRCS 2015) do not provide the information needed to assign different land use
35 subcategories to settlements, such as turf grass and impervious surfaces, which is needed to apply the Tier 1 factors
36 from the IPCC guidelines (2006). Therefore, the United States has adopted a land use factor of 0.7 to represent the
37 loss of carbon with conversion to settlements, which is similar to the estimated losses with conversion to cropland.
38 More specific factor values can be derived in future inventories as data become available. See Annex 3.12 for
39 additional discussion of the Tier 2 methodology for mineral soils.

40 *Organic Soil Carbon Stock Changes*

41 Annual C emissions from drained organic soils in *Land Converted to Settlements* are estimated using the Tier 2
42 method provided in IPCC (2006). The Tier 2 method assumes that organic soils are losing C at a rate similar to
43 croplands, and therefore uses the country-specific values for cropland (Ogle et al. 2003). To estimate CO₂ emissions,
44 the total area of organic soils in *Land Converted to Settlements* is multiplied by the Tier 2 emission factor, which is
45 11.2 MMT C per ha in cool temperate regions, 14.0 MMT C per ha in warm temperate regions and 11.2 MMT C per
46 ha in subtropical regions (See Annex 3.12 for more information).

1 Uncertainty and Time-Series Consistency

2 The uncertainty analysis for C losses with *Forest Land Converted to Settlements* is conducted in the same way as the
 3 uncertainty assessment for forest ecosystem C flux in the *Forest Land Remaining Forest Land* category. Sample and
 4 model-based error are combined using simple error propagation methods provided by the IPCC (2006). For
 5 additional details see the Uncertainty Analysis in Annex 3.13. The uncertainty analysis for mineral soil C stock
 6 changes and annual C emission estimates from drained organic soils in *Land Converted to Settlements* is estimated
 7 using a Monte Carlo approach, which is also described in the *Cropland Remaining Cropland* section.

8 Uncertainty estimates are presented in Table 6-86 for each subsource (i.e., biomass C stocks, mineral soil C stocks
 9 and organic soil C stocks) and the method applied in the inventory analysis (i.e., Tier 2 and Tier 3). Uncertainty
 10 estimates from the Tier 2 and 3 approaches are combined using the simple error propagation methods provided by
 11 the IPCC (2006), i.e., by taking the square root of the sum of the squares of the standard deviations of the uncertain
 12 quantities. The combined uncertainty for total C stocks in *Land Converted to Settlements* ranges from 4 percent
 13 below to 4 percent above the 2015 stock change estimate of 150.2 MMT CO₂ Eq.

14 **Table 6-86: Approach 2 Quantitative Uncertainty Estimates for C Stock Changes occurring**

16 Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990
 17 through 2015. Details on the emission trends through time are described in more detail in the Methodology section,
 18 above.

1 QA/QC and Verification

2 Quality control measures included checking input data, model scripts, and results to ensure data are properly
3 handled throughout the inventory process. Inventory reporting forms and text are reviewed and revised as needed to
4 correct transcription errors.

5 Planned Improvements

6 A planned improvement for the *Land Converted to Settlements* category is to develop an inventory of C stock
7 changes in Alaska. This includes C stock changes for biomass, dead organic matter and soils. There are also plans to
8 extend the Inventory to included C losses associated with drained organic soils in settlements occurring on federal
9 lands.

10 6.12 Other Land Remaining Other Land 11 (IPCC Source Category 4F1)

12 Land use is constantly occurring, and areas under a number of differing land-use types remain in their respective
13 land-use type each year, just as other land can remain as other land. While the magnitude of *Other Land Remaining*
14 *Other Land* is known (see Table 6-7), research is ongoing to track C pools in this land use. Until such time that
15 reliable and comprehensive estimates of C for *Other Land Remaining Other Land* can be produced, it is not possible
16 to estimate CO₂, CH₄ or N₂O fluxes on *Other Land Remaining Other Land* at this time.

17 6.13 Land Converted to Other Land (IPCC 18 Source Category 4F2)

19 Land-use change is constantly occurring, and areas under a number of differing land-use types are converted to other
20 land each year, just as other land is converted to other uses. While the magnitude of these area changes is known
21 (see Table 6-7), research is ongoing to track C across *Other Land Remaining Other Land* and *Land Converted to*
22 *Other Land*. Until such time that reliable and comprehensive estimates of C across these land-use and land-use
23 change categories can be produced, it is not possible to separate CO₂, CH₄ or N₂O fluxes on *Land Converted to*
24 *Other Land* from fluxes on *Other Land Remaining Other Land* at this time.

7. Waste

Waste management and treatment activities are sources of greenhouse gas emissions (see Figure 7-1). Landfills accounted for approximately 17.7 percent of total U.S. anthropogenic methane (CH₄) emissions in 2015, the third largest contribution of any CH₄ source in the United States. Additionally, wastewater treatment and composting of organic waste accounted for approximately 2.3 percent and 0.3 percent of U.S. CH₄ emissions, respectively. Nitrous oxide (N₂O) emissions from the discharge of wastewater treatment effluents into aquatic environments were estimated, as were N₂O emissions from the treatment process itself. Nitrous oxide emissions from composting were also estimated. Together, these waste activities account for 2.1 percent of total U.S. N₂O emissions. Nitrogen oxides (NO_x), carbon monoxide (CO), and non-CH₄ volatile organic compounds (NMVOCs) are emitted by waste activities, and are addressed separately at the end of this chapter. A summary of greenhouse gas emissions from the Waste chapter is presented in Table 7-1 and Table 7-2.

Figure 7-1: 2015 Waste Chapter Greenhouse Gas Sources (MMT CO₂ Eq.)

Overall, in 2015, waste activities generated emissions of 139.4 MMT CO₂ Eq., or 2.1 percent of total U.S. greenhouse gas emissions.

Table 7-1: Emissions from Waste (MMT CO₂ Eq.)

Gas/Source	1990	2005	2011	2012	2013	2014	2015
CH₄	195.6	152.1	136.2	137.9	133.7	133.5	132.6
Landfills	179.6	134.3	119.0	120.8	116.7	116.6	115.7

Wastewater Treatment	11	15	16	16	16	16	17
Composting	1	6	6	6	6	6	6

Note: Totals may not sum due to independent rounding.

2 Carbon dioxide (CO₂), CH₄, and N₂O emissions from the incineration of waste are accounted for in the Energy
 3 sector rather than in the Waste sector because almost all incineration of municipal solid waste (MSW) in the United
 4 States occurs at waste-to-energy facilities where useful energy is recovered. Similarly, the Energy sector also
 5 includes an estimate of emissions from burning waste tires and hazardous industrial waste, because virtually all of
 6 the combustion occurs in industrial and utility boilers that recover energy. The incineration of waste in the United
 7 States in 2015 resulted in 11.0 MMT CO₂ Eq. emissions, more than half of which is attributable to the combustion
 8 of plastics. For more details on emissions from the incineration of waste, see Section 7.4.

9 **Box 7-1: Waste Data from the Greenhouse Gas Reporting Program – TO BE UPDATED FOR FINAL INVENTORY**
 10 **REPORT**

On October 30, 2009, the U.S. EPA published a rule for the mandatory reporting of greenhouse gases from large greenhouse gas emissions sources in the United States. Implementation of 40 CFR Part 98 is referred to as EPA’s Greenhouse Gas Reporting Program (GHGRP). 40 CFR Part 98 applies to direct greenhouse gas emitters, fossil fuel suppliers, industrial gas suppliers, and facilities that inject CO₂ underground for sequestration or other reasons and requires reporting by 41 industrial categories. Reporting is at the facility level, except for certain suppliers of fossil fuels and industrial greenhouse gases. In general, the threshold for reporting is 25,000 metric tons or more of CO₂ Eq. per year.

EPA’s GHGRP dataset and the data presented in this Inventory report are complementary and, as indicated in the respective planned improvements sections for source categories in this chapter, EPA is analyzing how to use facility-level GHGRP data to improve the national estimates presented in this Inventory. Most methodologies used in EPA’s GHGRP are consistent with IPCC, though for EPA’s GHGRP, facilities collect detailed information specific to their operations according to detailed measurement standards. This may differ with the more aggregated data collected for the Inventory to estimate total, national U.S. emissions. It should be noted that the definitions for source categories in EPA’s GHGRP may differ from those used in this Inventory in meeting the UNFCCC reporting guidelines. In line with the UNFCCC reporting guidelines, the Inventory report is a comprehensive accounting of all emissions from source categories identified in the *2006 IPCC Guidelines* (IPCC 2006). Further information on the reporting categorizations in EPA’s GHGRP and specific data caveats associated with monitoring methods in EPA’s GHGRP has been provided on the EPA’s GHGRP website.¹

EPA presents the data collected by EPA’s GHGRP through a data publication tool that allows data to be viewed in several formats including maps, tables, charts and graphs for individual facilities or groups of facilities.²

² See <<http://ghgdata.epa.gov>>.

7.1 Landfills (IPCC Source Category 5A1)

In the United States, solid waste is managed by landfilling, recovery through recycling or composting, and combustion through waste-to-energy facilities (see Box 7-3). Disposing of solid waste in modern, managed landfills is the most commonly used waste management technique in the United States. More information on how solid waste data are collected and managed in the United States is provided in Box 7-2. The municipal solid waste (MSW) and industrial waste landfills referred to in this section are all modern landfills that must comply with a variety of regulations as discussed in Box 7-4. Disposing of waste in illegal dumping sites is not considered to have occurred in years later than 1980 and these sites are not considered to contribute to net emissions in this section for the timeframe of 1990 to the current Inventory year. MSW landfills, or sanitary landfills, are sites where MSW is managed to prevent or minimize health, safety, and environmental impacts. Waste is deposited in different cells and covered daily with soil; many have environmental monitoring systems to track performance, collect leachate, and collect landfill gas. Industrial waste landfills are constructed in a similar way as MSW landfills, but accept waste produced by industrial activity, such as factories, mills, and mines.

After being placed in a landfill, organic waste (such as paper, food scraps, and yard trimmings) is initially decomposed by aerobic bacteria. After the oxygen has been depleted, the remaining waste is available for consumption by anaerobic bacteria, which break down organic matter into substances such as cellulose, amino acids, and sugars. These substances are further broken down through fermentation into gases and short-chain organic compounds that form the substrates for the growth of methanogenic bacteria. These methane (CH₄) producing anaerobic bacteria convert the fermentation products into stabilized organic materials and biogas consisting of approximately 50 percent biogenic carbon dioxide (CO₂) and 50 percent CH₄, by volume. Landfill biogas also contains trace amounts of non-methane organic compounds (NMOC) and volatile organic compounds (VOC) that either result from decomposition by-products or volatilization of biodegradable wastes (EPA 2008).

Methane and CO₂ are the primary constituents of landfill gas generation and emissions. However, the 2006 *Intergovernmental Panel on Climate Change (IPCC) Guidelines* set an international convention to not report biogenic CO₂ released due to landfill decomposition in the Waste sector (IPCC 2006). Carbon dioxide emissions from landfills are estimated and reported under the Land Use, Land-Use Change, and Forestry (LULUCF) sector. Additionally, emissions of NMOC and VOC are not estimated because they are considered to be emitted in trace amounts. Nitrous oxide (N₂O) emissions from the disposal and application of sewage sludge on landfills are also not explicitly modeled as part of greenhouse gas emissions from landfills. Nitrous oxide emissions from sewage sludge applied to landfills as a daily cover or for disposal are expected to be relatively small because the microbial environment in an anaerobic landfill is not very conducive to the nitrification and denitrification processes that result in N₂O emissions. Furthermore, the 2006 *IPCC Guidelines* did not include a methodology for estimating N₂O emissions from solid waste disposal sites “because they are not significant.” Therefore, only CH₄ generation and emissions are estimated for landfills under the Waste sector.

Methane generation and emissions from landfills are a function of several factors, including: (1) the total amount of waste-in-place, which is the total waste landfilled annually over the operational lifetime of a landfill; (2) the characteristics of the landfill receiving waste (e.g., composition of waste-in-place, size, climate, cover material); (3) the amount of CH₄ that is recovered and either flared or used for energy purposes; and (4) the amount of CH₄ oxidized as the landfill gas – that is not collected by a gas collection system – passes through the cover material into the atmosphere. Each landfill has unique characteristics, but all managed landfills employ similar operating practices, including the application of a daily and intermediate cover material over the waste being disposed of in the landfill to prevent odor and reduce risks to public health. Based on recent literature, the specific type of cover material used can affect the rate of oxidation of landfill gas (RTI 2011). The most commonly used cover materials are soil, clay, and sand. Some states also permit the use of green waste, tarps, waste derived materials, sewage sludge or biosolids, and contaminated soil as a daily cover. Methane production typically begins within the first year after the waste is disposed of in a landfill and will continue for 10 to 60 years or longer as the degradable waste decomposes over time.

In 2015, landfill CH₄ emissions were approximately 115.7 MMT CO₂ Eq. (4,628 kt), representing the third largest source of CH₄ emissions in the United States, behind natural gas systems and enteric fermentation. Emissions from MSW landfills accounted for approximately 95 percent of total landfill emissions, while industrial landfills accounted for the remainder. Estimates of operational MSW landfills in the United States have ranged from 1,900 to

1 2,000 facilities (EPA 2016a; EPA 2016b; WBJ 2010). More recently, the Environment Research & Education
 2 Foundation conducted a nationwide analysis of MSW management, and counted 1,540 operational MSW landfills in
 3 2013 (EREF 2016). Conversely, there are approximately 3,200 MSW landfills in the United States that have been
 4 closed since 1980 (for which a closure date is known) (EPA 2016a; WBJ 2010). While the number of active MSW
 5 landfills has decreased significantly over the past 20 years, from approximately 6,326 in 1990 to 1,540 in the 2013,
 6 the average landfill size has increased (EREF 2016; EPA 2016b; BioCycle 2010). While the exact number of active
 7 and closed industrial waste landfills exist in the United States, the number of them is relatively low compared to
 8 MSW landfills. The Waste Business Journal database (WBJ 2010) includes a total for 1,305 landfills accepting
 9 industrial and construction and demolition debris for 2010 (WBJ 2010). Only 176 facilities with industrial waste
 10 landfills met the reporting threshold under Subpart TT (Industrial Waste Landfills) of EPA’s Greenhouse Gas
 11 Reporting Program (GHGRP), indicating that there may be several hundreds of industrial waste landfills that are not
 12 required to report under EPA’s GHGRP.

13 The annual amount of MSW generated and subsequently disposed in MSW landfills varies annually and depends on
 14 several factors (e.g., the economy, consumer patterns, recycling and composting programs, inclusion in a garbage
 15 collection service). The estimated annual quantity of waste placed in MSW landfills increased 10 percent from
 16 approximately 205.1 MMT in 1990 to 226.4 MMT in 2000 and then decreased by 11 percent to 203.4 MMT in 2015
 17 (see Annex 3.14). The total amount of MSW generated is expected to increase as the U.S. population continues to
 18 grow, but the percentage of waste landfilled may decline due to increased recycling and composting practices. The
 19 estimated quantity of waste placed in industrial waste landfills (from the pulp and paper, and food processing
 20 sectors) has remained relatively steady since 1990, ranging from 9.7 MMT in 1990 to 10.5 MMT in 2015.

21 Net CH₄ emissions from MSW landfills have decreased since 1990. In 1990, approximately 0.7 MMT of CH₄ were
 22 recovered and combusted from landfills (see Table 7-4), while in 2015, approximately 7.4 MMT of CH₄ were
 23 recovered and combusted, representing an average annual increase in the quantity of CH₄ recovered and combusted
 24 at MSW landfills from 1990 to 2015 of 11 percent (see Annex 3.14). The decreasing trend since the 1990s can be
 25 mostly attributed to increased use of gas collection and control systems, and a reduction of decomposable materials
 26 (i.e., paper and paperboard, food scraps, and yard trimmings) discarded in MSW landfills over the time series. The
 27 quantity of recovered CH₄ that is collected and either flared or used for energy purposes at MSW landfills has
 28 continually increased as a result of 1996 federal regulations that require large MSW landfills to collect and combust
 29 landfill gas (see 40 CFR Part 60, Subpart Cc 2005 and 40 CFR Part 60, Subpart WWW 2005). Voluntary programs
 30 that encourage CH₄ recovery and beneficial reuse, such as EPA’s Landfill Methane Outreach Program (LMOP) and
 31 federal and state incentives that promote renewable energy (e.g., tax credits, low interest loans, and Renewable
 32 Portfolio Standards), have also contributed to increased interest in landfill gas collection and control.

33 In 2015, an estimated 11 new landfill gas-to-energy (LFGTE) projects (EPA 2016a) began operation. While the
 34 amount of landfill gas collected and combusted continues to increase, the rate of increase in collection and
 35 combustion no longer exceeds the rate of additional CH₄ generation from the amount of organic MSW landfilled as
 36 the U.S. population grows.

37 Landfill gas collection and control is not accounted for at industrial waste landfills in this chapter (see the
 38 Methodology discussion for more information).

39 **Table 7-3: CH₄ Emissions from Landfills (MMT CO₂ Eq.)**

Activity	1990	2005	2011	2012	2013	2014	2015
MSW CH ₄ Generation	205.3	-	-	-	-	-	-
Industrial CH ₄ Generation	12.1	15.9	16.4	16.5	16.5	16.6	16.6
MSW CH ₄ Recovered	(17.9)	-	-	-	-	-	-
MSW CH ₄ Oxidized	(18.7)	-	-	-	-	-	-
Industrial CH ₄ Oxidized	(1.2)	(1.6)	(1.6)	(1.6)	(1.7)	(1.7)	(1.7)
MSW net CH ₄ Emissions (GHGRP)	-	120.0	104.2	106.0	101.9	101.7	100.8
Total	179.6	134.3	119.0	120.8	116.7	116.6	115.7

Notes: Totals may not sum due to independent rounding. For years 1990 to 2004, the Inventory methodology uses the first order decay methodology. A methodological change occurs in year 2005. For years 2005 to 2015, net CH₄ emissions from EPA’s GHGRP data are used. These data incorporate CH₄ recovered and oxidized. Parentheses indicate negative values.

1 **Table 7-4: CH₄ Emissions from Landfills (kt)**

Activity	1990	2005	2011	2012	2013	2014	2015
MSW CH ₄ Generation	8,214	-	-	-	-	-	-
Industrial CH ₄ Generation	484	636	657	659	661	662	662
MSW CH ₄ Recovered	(718)	-	-	-	-	-	-
MSW CH ₄ Oxidized	(750)	-	-	-	-	-	-
Industrial CH ₄ Oxidized	(48)	(64)	(66)	(66)	(66)	(66)	(66)
MSW net CH ₄ Emissions (GHGRP)	-	4,800	4,169	4,241	4,074	4,067	4,032
Total	7,182	5,372	4,760	4,834	4,669	4,663	4,628

Notes: Totals may not sum due to independent rounding. For years 1990 to 2004, the Inventory methodology uses the first order decay methodology. A methodological change occurs in year 2005. For years 2005 to 2015, net CH₄ emissions from EPA's GHGRP data are used. These data incorporate CH₄ recovered and oxidized. Parentheses indicate negative values.

2 Methodology

3 Methodology Applied for MSW Landfills

4 Methane emissions from landfills can be estimated using two primary methods. The first method uses the first order
 5 decay model as described by the *2006 IPCC Guidelines* to estimate CH₄ generation. The amount of CH₄ recovered
 6 and combusted from MSW landfills is subtracted from the CH₄ generation, and is then adjusted with an oxidation
 7 factor. The oxidation factor represents the amount of CH₄ in a landfill that is oxidized to CO₂ as it passes through
 8 the landfill cover (e.g., soil, clay, geomembrane, alternative daily cover). This method is presented below, and is
 9 similar to Equation HH-5 in CFR Part 98.343 for MSW landfills, and Equation TT-6 in CFR Part 98.463 for
 10 industrial waste landfills.

$$11 \quad \text{CH}_{4,\text{Solid Waste}} = [\text{CH}_{4,\text{MSW}} + \text{CH}_{4,\text{Ind}} - \text{R}] - \text{Ox}$$

12 where,

- 13 $\text{CH}_{4,\text{Solid Waste}}$ = Net CH₄ emissions from solid waste
- 14 $\text{CH}_{4,\text{MSW}}$ = CH₄ generation from MSW landfills
- 15 $\text{CH}_{4,\text{Ind}}$ = CH₄ generation from industrial landfills
- 16 R = CH₄ recovered and combusted (only for MSW landfills)
- 17 Ox = CH₄ oxidized from MSW and industrial waste landfills before release to the atmosphere

18 The second method used to calculate CH₄ emissions from landfills, also called the back calculation method, is based
 19 off of directly measured amounts of recovered CH₄ from the landfill gas and is expressed below and by Equation
 20 HH-8 in CFR Part 98.343. The two parts of the equation consider the portion of CH₄ in the landfill gas is not
 21 collected by the landfill gas collection system; and the portion that is collected. First, the recovered CH₄ is adjusted
 22 with the collection efficiency of the gas collection and control system and the fraction of hours the recovery system
 23 operated in the calendar year. This quantity represents the amount of CH₄ in the landfill gas that is not captured by
 24 the collection system; it is then adjusted for oxidation. The second portion of the equation adjusts the portion of CH₄
 25 in the collected landfill gas with the efficiency of the destruction device(s), and the fraction of hours the destruction
 26 device(s) operated during the year.

$$27 \quad \text{CH}_{4,\text{Solid Waste}} = \left[\left(\frac{\text{R}}{\text{CE} \times \text{f}_{\text{REC}}} - \text{R} \right) \times (1 - \text{OX}) + \text{R} \times (1 - (\text{DE} \times \text{f}_{\text{Dest}})) \right]$$

28 where,

- 29 R = Quantity of recovered CH₄ from Equation HH-4 of the GHGRP
- 30 CE = Collection efficiency estimated at the landfill, taking into account system coverage,
 31 operation, and cover system materials from Table HH-3 of the GHGRP. If area by soil
 32 cover type information is not available, the default value of 0.75 should be used. (percent)
- 33 f_{REC} = fraction of hours the recovery system was operating (percent)

1	OX	= oxidation factor (percent)
2	DE	= destruction efficiency (percent)
3	f _{Dest}	= fraction of hours the destruction device was operating (fraction)
4		

5 The current Inventory uses both methods to estimate CH₄ emissions across the time series. In previous Inventory
6 reports, only the first order decay method was used. Methodological changes have been made to the current
7 Inventory to incorporate higher tier data (i.e., CH₄ emissions directly reported to EPA’s GHGRP), which cannot be
8 directly applied to earlier years in the time series without significant bias. The overlap technique, as described in the
9 Methodological Recalculations section of this Inventory, and in the Time Series Consistency chapter of the 2006
10 *IPCC Guidelines*, was used to merge the higher tier data with the previously used method.

11 The first order decay method is exclusively used for 1990 to 2004. The CH₄ generation is based on nationwide
12 MSW generation data, to which a national average disposal factor is applied; it is not landfill-specific. The amount
13 of CH₄ recovered, however, is landfill-specific, but only for MSW landfills due to a lack of data specific to
14 industrial waste landfills. A combination of both methods are used for the rest of the time series (i.e., 2005 to 2015)
15 in this Inventory. Specifically, directly reported CH₄ emissions from EPA’s GHGRP are used for years they are
16 available (i.e., 2010 to 2015). Landfills reporting to EPA’s GHGRP without gas collection and control apply the first
17 order decay method, while the majority of landfills with landfill gas collection and control apply the back-
18 calculation method. The directly reported GHGRP emissions data were used to back-cast CH₄ emissions for 2005 to
19 2010. An overview of the data sources and methodology used to calculate CH₄ generation and recovery is provided
20 below, while a more detailed description of the methodology used to estimate CH₄ emissions from landfills can be
21 found in Annex 3.14.

22 **Description of the First Order Decay Methodology for MSW Landfills**

23 States and local municipalities across the United States do not consistently track and report quantities of MSW
24 generated or collected for management, nor are end-of-life disposal methods reported to a centralized system.
25 Therefore, national MSW landfill waste generation and disposal data are obtained from secondary data, specifically
26 the State of Garbage (SOG) surveys, published approximately every two years, with the most recent publication date
27 of 2014. The SOG survey was the only continually updated nationwide survey of waste disposed in landfills in the
28 United States and was the primary data source with which to estimate nationwide CH₄ generation from MSW
29 landfills. Now, EPA’s GHGRP waste disposal data and MSW management data published by EREF are available.
30 The SOG surveys use the principles of mass balance where all MSW generated is equal to the amount of MSW
31 landfilled, combusted in waste-to-energy plants, composted, and/or recycled (BioCycle 2010; Shin 2014). This
32 approach assumes that all waste management methods are tracked and reported to state agencies. Survey
33 respondents are asked to provide a breakdown of MSW generated and managed by landfilling, recycling,
34 composting, and combustion (in waste-to-energy facilities) in actual tonnages as opposed to reporting a percent
35 generated under each waste disposal option. The data reported through the survey have typically been adjusted to
36 exclude non-MSW materials (e.g., industrial and agricultural wastes, construction and demolition debris, automobile
37 scrap, and sludge from wastewater treatment plants) that may be included in survey responses. In the most recent
38 survey, state agencies were asked to provide already filtered, MSW-only data. Where this was not possible, they
39 were asked to provide comments to better understand the data being reported. All state disposal data are adjusted for
40 imports and exports across state lines where imported waste is included in a particular state’s total while exported
41 waste is not. Methodological changes have occurred over the time frame the SOG survey has been published, and
42 this has affected the fluctuating trends observed in the data (RTI 2013).

43 The SOG survey is voluntary and not all states provide data for each survey year. Where no waste generation data
44 are provided by a state in the SOG survey, the amount generated is estimated by multiplying the waste per capita
45 from a previous SOG survey by that particular state’s population. If that particular state did not report any waste
46 generation data in the previous SOG survey, the average nationwide waste per capita rate for the current SOG
47 survey is multiplied by that particular state’s population. The quantities of waste generated across all states are
48 summed and that value is then used as the nationwide quantity of waste generated in a given reporting year.

49 State-specific landfill MSW generation data and a national average disposal factor for 1989 through 2008 were
50 obtained from the SOG survey every two years (i.e., 2002, 2004, 2006, and 2008 as published in BioCycle 2006,
51 and 2008 as published in BioCycle 2010). The most recent SOG survey provides data for 2011 (Shin 2014). The
52 EREF published a report on MSW Management in the United States that includes state-specific landfill MSW

1 generation and disposal data for 2010 and 2013 using a similar methodology as the SOG surveys (EREF 2016).
2 State-specific landfill waste generation data for the years in-between the SOG surveys and EREF report (e.g., 2001,
3 2003, 2005, 2007, and 2009) were either interpolated or extrapolated based on the SOG or EREF data and the U.S.
4 Census population data. In the current Inventory methodology, the MSW generation and disposal data are no longer
5 used to estimate CH₄ emissions for the years 2005 to 2015 because EPA's GHGRP emissions data are now used for
6 those years. The MSW generation and disposal data for these years are still useful for examining general trends in
7 MSW management in the United States.

8 Estimates of the quantity of waste landfilled from 1989 to 2004 are determined by applying an average national
9 waste disposal factor to the total amount of waste generated (i.e., the SOG data). A waste disposal factor is
10 determined for each year an SOG survey is published and equals the ratio of the total amount of waste landfilled in
11 the United States to the total amount of waste generated in the United States. The waste disposal factor is
12 interpolated or extrapolated for the years in-between the SOG surveys, as is done for the amount of waste generated
13 for a given survey year.

14 The IPCC methodology recommends at least 50 years of waste disposal data in order to estimate CH₄ emissions.
15 Estimates of the annual quantity of waste landfilled for 1960 through 1988 were obtained from EPA's
16 *Anthropogenic Methane Emissions in the United States, Estimates for 1990: Report to Congress* (EPA 1993) and an
17 extensive landfill survey by the EPA's Office of Solid Waste in 1986 (EPA 1988). Although waste placed in
18 landfills in the 1940s and 1950s contributes very little to current CH₄ generation, estimates for those years were
19 included in the FOD model for completeness in accounting for CH₄ generation rates and are based on the population
20 in those years and the per capita rate for land disposal for the 1960s. For calculations in the current Inventory,
21 wastes landfilled prior to 1980 were broken into two groups: wastes disposed in landfills (Methane Conversion
22 Factor, MCF, of 1) and those disposed in dumps (MCF of 0.6). All calculations after 1980 assume waste is disposed
23 in managed, modern landfills. See Annex 3.14 for more details.

24 Methane recovery is currently only accounted for at MSW landfills. The estimated landfill gas recovered per year
25 (R) at MSW landfills was based on a combination of four databases and including recovery from flares and/or
26 landfill gas-to-energy projects:

- 27 • EPA's GHGRP dataset for MSW landfills (EPA 2015a);
- 28 • A database developed by the Energy Information Administration (EIA) for the voluntary reporting of
29 greenhouse gases (EIA 2007);
- 30 • A database of LFGTE projects that is primarily based on information compiled by the EPA LMOP (EPA
31 2016a); and
- 32 • The flare vendor database (contains updated sales data collected from vendors of flaring equipment).

33 The same landfill may be included one or more times across these four databases. To avoid double- or triple-
34 counting CH₄ recovery, the landfills across each database were compared and duplicates identified. A hierarchy of
35 recovery data is used based on the certainty of the data in each database. In summary, EPA's GHGRP > EIA >
36 LFGTE > flare vendor database. The rationale for this hierarchy is described below.

37 EPA's GHGRP MSW landfills database was first introduced as a data source for the 1990 to 2013 Inventory. EPA's
38 GHGRP MSW landfills database contains facility-reported data that undergoes rigorous verification, thus it is
39 considered to contain the least uncertain data of the four CH₄ recovery databases. However, as mentioned earlier,
40 this database is unique in that it only contains a portion of the landfills in the United States (although, presumably
41 the highest emitters since only those landfills that meet a certain CH₄ generation threshold must report) and only
42 contains data for 2010 and later. Directly reported values for CH₄ recovery to EPA's GHGRP are available for years
43 2010 through 2014. In the current Inventory methodology, methane recovery for 1990 to 2004 for facilities reporting
44 to EPA's GHGRP has been estimated using the directly reported emissions for those facilities from 2010 to 2015,
45 and an Excel forecasting function so that the GHGRP data source can be applied to earlier years in the time series.
46 Directly reported net CH₄ emissions from EPA's GHGRP are used for 2010 to 2015, and back-casted from 2009 to
47 2005. Prior to 2005, if a landfill in EPA's GHGRP was also in the LFGTE or EIA databases, the landfill gas project
48 information, specifically the project start year, from either the LFGTE or EIA databases was used as the cutoff year
49 for the estimated CH₄ recovery in the GHGRP database. For example, if a landfill reporting under EPA's GHGRP
50 was also included in the LFGTE database under a project that started in 2002 that is still operational, the CH₄
51 recovery data in the GHGRP database for that facility was back-calculated to the year 2002 only. This method,

1 although somewhat uncertain, can be refined in future Inventory reports after further investigating the landfill gas
2 project start years for landfills in the GHGRP database.

3 If a landfill in EPA's GHGRP MSW landfills database was also in the EIA, LFGTE, and/or flare vendor database,
4 the avoided emissions were only based on EPA's GHGRP MSW landfills database to avoid double or triple
5 counting the recovery amounts. In other words, the recovery from the same landfill was not included in the total
6 recovery from the EIA, LFGTE, or flare vendor databases.

7 If a landfill in the EIA database was also in the LFGTE and/or the flare vendor database, the CH₄ recovery was
8 based on the EIA data because landfill owners or operators directly reported the amount of CH₄ recovered using gas
9 flow concentration and measurements, and because the reporting accounted for changes over time. However, as the
10 EIA database only includes facility-reported data through 2006, the amount of CH₄ recovered for years 2007 and
11 later were assumed to be the same as in 2006 for landfills that are in the EIA database, but not in the GHGRP or
12 LFGTE databases. This quantity likely underestimates flaring because the EIA database does not have information
13 on all flares in operation for the years after 2006. However, nearly all (93 percent) of landfills in the EIA database
14 also report to EPA's GHGRP, which means that only seven percent of landfills in the EIA database are counted in
15 the total recovery.

16 If both the flare data and LFGTE recovery data were available for any of the remaining landfills (i.e., not in the EIA
17 or GHGRP databases), then the avoided emissions were based on the LFGTE data, which provides reported landfill-
18 specific data on gas flow for direct use projects and project capacity (i.e., megawatts) for electricity projects. The
19 LFGTE database is based on the most recent EPA LMOP database (published annually). The remaining portion of
20 avoided emissions is calculated by the flare vendor database, which estimates CH₄ combusted by flares using the
21 midpoint of a flare's reported capacity. New flare vendor sales data were unable to be obtained for the current
22 Inventory year. Given that each LFGTE project is likely to also have a flare, double counting reductions from flares
23 and LFGTE projects in the LFGTE database was avoided by subtracting emission reductions associated with
24 LFGTE projects for which a flare had not been identified from the emission reductions associated with flares
25 (referred to as the flare correction factor). A further explanation of the methodology used to estimate the landfill gas
26 recovered can be found in Annex 3.14.

27 The destruction efficiencies reported through EPA's GHGRP were applied to the landfills in the GHGRP MSW
28 landfills database. The median value of the reported destruction efficiencies was 99 percent for all reporting years
29 (2010 through 2015). A destruction efficiency of 99 percent was applied to CH₄ recovered to estimate CH₄
30 emissions avoided due to the combusting of CH₄ in destruction devices (i.e., flares) in the EIA, LFGTE, and flare
31 vendor databases. The 99 percent destruction efficiency value selected was based on the range of efficiencies (86 to
32 greater than 99 percent) recommended for flares in EPA's *AP-42 Compilation of Air Pollutant Emission Factors*,
33 Draft Section 2.4, Table 2.4-3 (EPA 2008). A typical value of 97.7 percent was presented for the non-CH₄
34 components (i.e., volatile organic compounds and non-methane organic compounds) in test results (EPA 2008). An
35 arithmetic average of 98.3 percent and a median value of 99 percent are derived from the test results presented in
36 EPA (2008). Thus, a value of 99 percent for the destruction efficiency of flares has been used in the Inventory
37 methodology. Other data sources supporting a 99 percent destruction efficiency include those used to establish New
38 Source Performance Standards (NSPS) for landfills and in recommendations for shutdown flares used by the EPA
39 LMOP.

40 The amount of CH₄ oxidized by the landfill cover at both municipal and industrial waste landfills was assumed to be
41 10 percent of the CH₄ generated that is not recovered (IPCC 2006; Mancinelli and McKay 1985; Czepiel et al. 1996)
42 for the years 1990 to 2004. For years 2005 to 2015, the current Inventory methodology uses directly reported net
43 CH₄ emissions from EPA's GHGRP, or back-casted emissions based on the directly reported data. EPA's GHGRP
44 data allows facilities to apply a range of oxidation factors (0.0, 0.10, 0.25, or 0.35) based on the calculated CH₄ flux
45 at the landfill.

46 For the years 1990 to 2004, net CH₄ emissions are calculated by subtracting the CH₄ recovered and CH₄ oxidized
47 from CH₄ generated at municipal and industrial waste landfills. For the years 2005 and onward, the same
48 methodology may be used, or the back-calculation approach may be used (Equation HH-8 in CFR Part 98.343, as
49 described above). The back-calculation approach starts with the amount of CH₄ recovered and works back through
50 the system to account for the amount of gas not collected by the landfill gas collection and control system (i.e., the
51 collection efficiency). An oxidation factor (0.0, 0.10, 0.25, or 0.35) is applied to the amount of CH₄ recovered
52 divided by the collection efficiency, subtracted from the amount of CH₄ recovered.

1 **Description of the GHGRP Data for MSW Landfills**

2 Directly reported CH₄ emissions, or back-casted emissions based off EPA’s GHGRP dataset were applied for years
3 2005 to 2015. Under the GHGRP methodology, the first order decay model methodology, adjusted for oxidation is
4 applied to estimate CH₄ generation for landfills without landfill gas collection and control. Landfills with gas
5 collection and control are required to estimate CH₄ emissions two ways; one that is based off of the first order decay
6 methodology, and a second that is based off of directly measured amounts of recovered landfill gas (Equation HH-8
7 in CFR Part 98.343, as described above). The GHGRP details allowable methodologies for monitoring quantities of
8 recovered CH₄ from the landfill gas, and the EPA verifies all annual greenhouse gas reports.

9 **Description of the First Order Decay Methodology for Industrial Waste Landfills**

10 Emissions from industrial waste landfills were estimated from industrial production data from 2014 extrapolated to
11 2015 (ERG 2016), waste disposal factors, and the FOD model. The Inventory methodology assumes over 99 percent
12 of the organic waste placed in industrial waste landfills originates from the food processing (meat, vegetables, fruits)
13 and pulp and paper sectors (EPA 1993), thus estimates of industrial landfill emissions focused on these two sectors.
14 There are currently no data sources that track and report the amount and type of waste disposed of in the universe of
15 industrial waste landfills in the United States. EPA’s GHGRP provides some insight into waste disposal in industrial
16 waste landfills and supports the focus of the Inventory on the two selected sectors, but is not comprehensive.
17 Therefore, the amount of waste landfilled is assumed to be a fraction of production that is held constant over the
18 time series as explained in Annex 3.14. The composition of waste disposed of in industrial waste landfills is
19 expected to be more consistent in terms of composition and quantity than that disposed of in MSW landfills.

20 Data collected through EPA’s GHGRP for industrial waste landfills (Subpart TT) show that only two of the 176
21 facilities, or 1 percent of facilities, have active gas collection systems (EPA 2015a). EPA’s GHGRP is not a national
22 database and comprehensive data regarding gas collection systems have not been published for industrial waste
23 landfills. Assumptions regarding a percentage of landfill gas collection systems, or a total annual amount of landfill
24 gas collected for the non-reporting industrial waste landfills have not been made for the Inventory methodology.

25 **Uncertainty and Time-Series Consistency – TO BE UPDATED** 26 **FOR FINAL INVENTORY REPORT**

27 Several types of uncertainty are associated with the estimates of CH₄ emissions from MSW and industrial waste
28 landfills when the first order decay model is applied. The approach used in the MSW emission estimates assumes
29 that the CH₄ generation potential (L₀) and the rate of decay that produces CH₄ from MSW, as determined from
30 several studies of CH₄ recovery at MSW landfills, are representative of conditions at U.S. MSW landfills. When this
31 top-down approach is applied at the nationwide level, the uncertainties are assumed to be less than when applying
32 this approach to individual landfills and then aggregating the results to the national level. In other words, the first
33 order decay methodology as applied in this Inventory is not facility-specific modeling and while this approach may
34 over- or under-estimate CH₄ generation at some landfills if used at the facility-level, the end result is expected to
35 balance out because it is being applied nationwide. There is also a high degree of uncertainty and variability
36 associated with the FOD model, particularly when a homogeneous waste composition and hypothetical
37 decomposition rates are applied to heterogeneous landfills (IPCC 2006).

38 The lack of landfill-specific information regarding the number and type of industrial waste landfills in the United
39 States is a primary uncertainty with respect to the industrial waste generation and emissions estimates. The approach
40 used here assumes that the majority (99 percent) of industrial waste disposed of in industrial waste landfills consists
41 of waste from the pulp and paper and food processing sectors. However, because waste generation and disposal data
42 are not available in an existing data source for all U.S. industrial waste landfills, a straight disposal factor is applied
43 over the entire time series to the amount of waste generated to determine the amounts disposed. Industrial waste
44 facilities reporting under EPA’s GHGRP do report detailed waste stream information, and these data have been used
45 to improve, for example, the DOC value used in the Inventory methodology for the pulp and paper sector.

46 Aside from the uncertainty in estimating landfill CH₄ generation, uncertainty also exists in the estimates of the
47 landfill gas oxidized. A constant oxidation factor of 10 percent as recommended by the IPCC for managed landfills
48 is used for both MSW and industrial waste landfills regardless of climate, the type of cover material, and/or presence

of a gas collection system. The number of published field studies measuring the rate of oxidation has increased substantially since the 2006 IPCC Guidelines were published and, as discussed in the Potential Improvements section, efforts are being made to review the literature and revise this value based on recent, peer-reviewed studies.

Another significant source of uncertainty lies with the estimates of CH₄ recovered by flaring and gas-to-energy projects at MSW landfills. The GHGRP MSW landfills database was added as a fourth recovery database starting with the 1990 through 2013 Inventory report. Relying on multiple databases for a complete picture introduces uncertainty because the coverage and characteristics of each database differs, which increases the chance of double counting avoided emissions. Additionally, the methodology and assumptions that go into each database differ. For example, the flare database assumes the midpoint of each flare capacity at the time it is sold and installed at a landfill; in reality, the flare may be achieving a higher capacity, in which case the flare database would underestimate the amount of CH₄ recovered.

The LFGTE database is updated annually. The flare database is populated by the voluntary sharing of flare sales data by select vendors and is not able to be obtained annually, which likely underestimates recovery for landfills not included in the three other recovery databases used by the Inventory. The EIA database has not been updated since 2006 and has, for the most part, been replaced by the GHGRP MSW landfills database. To avoid double counting and to use the most relevant estimate of CH₄ recovery for a given landfill, a hierarchical approach is used among the four databases. GHGRP data are given precedence because CH₄ recovery is directly reported by landfills and undergoes a rigorous verification process; the EIA data are given second priority because facility data were directly reported; the LFGTE data are given third priority because CH₄ recovery is estimated from facility-reported LFGTE system characteristics; and the flare data are given fourth priority because this database contains minimal information about the flare, no site-specific operating characteristics, and includes smaller landfills not included in the other three databases (Bronstein et al. 2012). The coverage provided across the databases most likely represents the complete universe of landfill CH₄ gas recovery; however, the number of unique landfills between the four databases does differ.

The IPCC default value of 10 percent for uncertainty in recovery estimates was used for two of the four recovery databases in the uncertainty analysis where metering of landfill gas was in place (for about 64 percent of the CH₄ estimated to be recovered). This 10 percent uncertainty factor applies to the LFGTE database; 12 percent to the EIA database; and 1 percent for the GHGRP MSW landfills dataset because of the supporting information provided and rigorous verification process. For flaring without metered recovery data (the flare database), a much higher uncertainty value of 50 percent is used. The compounding uncertainties associated with the four databases in addition to the uncertainties associated with the FOD model and annual waste disposal quantities leads to the large upper and lower bounds for MSW landfills presented in Table 7-5. Industrial waste landfills are shown with a lower range of uncertainty due to the smaller number of data sources and associated uncertainty involved. For example, three data sources are used to generate the annual quantities of MSW waste disposed over the 1940 to current year timeframe, while industrial waste landfills rely on two data sources.

There is less uncertainty in the GHGRP data because this methodology is facility-specific, uses directly measured CH₄ recovery data (when applicable), and allows for a variety of landfill gas collection efficiencies, destruction efficiencies, and/or oxidation factors to be used.

The results of the 2006 IPCC Guidelines Approach 2 quantitative uncertainty analysis are summarized in Table 7-5.

Table 7-5: Approach 2 Quantitative Uncertainty Estimates for CH₄ Emissions from Landfills (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			(MMT CO ₂ Eq.)		(%)	
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Landfills	CH₄					
MSW	CH ₄					
Industrial	CH ₄					

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

1 QA/QC and Verification

2 A Quality Assurance/Quality Control (QA/QC) analysis is performed each Inventory year. QA/QC checks are
3 performed for the transcription of the published data set used to populate the Inventory data set, including the
4 published GHGRP, LFGTE, and flare databases. While preparing the Inventory, QA/QC checks are not performed
5 on the data itself against primary data used. EPA verifies annual reports from Subpart HH through a multi-step
6 process (e.g., combination of electronic checks and manual reviews) to identify potential errors and ensure that data
7 submitted to EPA are accurate, complete, and consistent.³ A primary focus of the QA/QC checks in past Inventory
8 reports was to ensure that CH₄ recovery estimates were not double-counted and that all LFGTE projects and flares
9 were included in the respective project databases. QA/QC checks performed in the past for the recovery databases
10 were not performed in this Inventory because new data were not added to the recovery databases for 2015.

11 The primary calculation spreadsheet is tailored from the IPCC waste model and has been verified previously using
12 the original, peer-reviewed IPCC waste model. All model input values were verified by secondary QA/QC review.

13 Recalculations Discussion

14 Four major methodological recalculations were performed for the current Inventory.

- 15 • First, net CH₄ emissions as directly reported to subpart HH of EPA's GHGRP were used for 2010 to 2015.
- 16 • Second, a 12.5 percent scale-up factor was applied to the subpart HH data to account for emission from
17 MSW landfills that are not required to report under subpart HH.
- 18 • Third, the net CH₄ emissions from 2010 to 2015 from subpart HH were used to estimate, or back-cast, net
19 CH₄ emissions for 2005 to 2009.
- 20 • Fourth, the previously used method, which relies on the first order decay model, was applied with revised
21 MSW generation data for years 1990 to 2004.

22 A detailed description of these methodological changes are included below.

23 **Using directly reported net CH₄ emissions from the GHGRP.** The EPA has relied on a top-down approach to
24 calculate CH₄ generation for MSW landfills in previous Inventory reports. The *SOG survey* has been used in
25 previous Inventories, but is no longer being published as routinely as it has been in the past. Therefore, EPA
26 investigated whether a bottom-up (or landfill-specific) approach could be used in future Inventories by either
27 supplementing the GHGRP annual waste disposal data with other relevant datasets (e.g., LMOP, state data) to
28 provide the annual waste disposal data needed for the FOD model; or, using directly reported net CH₄ emissions
29 from EPA's GHGRP. EPA's GHGRP requires landfills meeting or exceeding a threshold of 25,000 metric tons of
30 CH₄ generation per year to report a variety of facility-specific information, including historical and current waste
31 disposal quantities by year, CH₄ generation, gas collection system details, CH₄ recovery, and CH₄ emissions. EPA
32 decided upon using the directly reported net CH₄ emissions data for the years the data are available (i.e., 2010 to
33 2015). These data are considered to be Tier 3 data (the highest quality) under the *2006 IPCC Guidelines*, and
34 undergo an extensive QA/QC review and verification process by EPA. Additionally, these data incorporate
35 oxidation factors that align with recent literature. The Inventory still applies an oxidation factor of 0.10 and a DOC
36 value of 0.2028 to the bulk MSW disposed in landfills for the years 1990 to 2004.

37 **Applying a scale-up factor to the GHGRP data.** The landfills reporting to EPA's GHGRP are considered the
38 largest emitters, but not all landfills are required to report. When this dataset is supplemented with others, such as
39 the EPA LMOP data and the Waste Business Journal data, a complete data set of the annual quantity of waste
40 landfilled may be represented. EPA is continuing to investigate the number of non-reporting landfills to the GHGRP
41 and the total annual quantities of CH₄ emissions from these non-reporting landfills. For this Inventory, EPA has
42 applied a scale-up factor of 12.5 percent to the GHGRP net CH₄ emissions to account for the non-reporting landfills.
43 This scale-up factor may be revised in future years after a thorough review of available data for the non-reporting
44 landfills is completed.

³ See <https://www.epa.gov/sites/production/files/2015-07/documents/ghgrp_verification_factsheet.pdf>.

1 **Back-casting net CH₄ emissions from the GHGRP.** The EPA also investigated various back-casting approaches to
2 estimate CH₄ emissions throughout the entire time series (back to 1990) while relying solely on EPA’s GHGRP
3 emissions data. Back-casting this far back with a limited set of data is not recommended in Volume 1: Chapter 5 of
4 the *2006 IPCC Guidelines*, which provides best practices for time series consistency when implementing
5 methodological changes and refinements. Plotting the GHGRP back-casted emissions against the emissions
6 estimates from the previously used method showed an alignment of the data in 2004 and later years. The *2006 IPCC*
7 *Guidelines* recommend using a splicing technique if the data overlap for a period of years as the data do with the
8 revised methodology. Therefore, EPA decided to back-cast the GHGRP emissions from 2009 to 2005 only, while
9 also applying the 12.5 percent scale-up factor to the back-casted GHGRP data.

10 **Recalculations to the MSW generation and disposal data and CH₄ generation estimates.** The revised
11 methodology relies on the previous methodology for the years 1990 to 2004, whereby a disposal factor is applied to
12 nationwide, annual MSW generation amounts. The MSW generation data were modified from the previous
13 Inventory for years 1990 to 2013 to reflect recently published data (i.e., EREF 2016), and to align with how MSW
14 quantities are applied under Subpart HH of the GHGRP to estimate CH₄ generation. Revisions were made to the
15 SOG survey data applied by the Inventory to exclude construction and demolition (C&D) waste and inerts from the
16 annual quantities of MSW generated used in the first order decay model. Years that EPA has “hard” data for MSW
17 generation include 2002, 2004, 2006, 2008, 2010, and 2013. EPA used MSW generation data and population
18 changes for those years to extrapolate MSW generation for years 1990 and 2001. EPA used the 2002 and 2004 data
19 to interpolate MSW generation for 2003.

20 **Merging methodologies for time series consistency.** Volume 1: Chapter 5 of the *2006 IPCC Guidelines* provides
21 guidance on good practices for time series consistency. As stated in this chapter, “the time series is a central
22 component of the greenhouse gas inventory because it provides information on historical emissions trends and tracks
23 the effects of strategies to reduce emissions at the national level. All emissions estimates in a time series should be
24 estimated consistently, which means that as far as possible, the time series should be calculated using the same
25 method and data sources in all years.” This chapter also provides guidance on techniques to splice, or join
26 methodologies together. EPA’s GHGRP data are considered higher tier data compared to the national MSW
27 generation estimates, and a new methodology was required to apply the GHGRP data to the Inventory because it is
28 only available for a portion of the time series.

29 The overlap technique is an example of a splicing technique. Other examples of splicing techniques include
30 surrogate data, interpolation, and extrapolation. The overlap technique can be used when new data become available
31 that cannot be applied to earlier years in the time series (IPCC 2006). EPA developed a time series based on the
32 relationship (or overlap) observed between the two methods (the previous method and the new method) during the
33 years when both methods align and can be used. The previously used method in this instance is based on the first
34 order decay model and national MSW generation estimates. The new method refers to EPA’s GHGRP data (for
35 years 2010 to 2015, and back-casted estimates for years 1990 to 2009). Figure 7-2 shows how the revised Inventory
36 methodology compares to back-casting the directly reported GHGRP data for MSW landfills. EPA decided to apply
37 the previously used method for the earlier years in the time series (i.e., 1990 to 2004), and the new method for later
38 years (i.e., 2005 to 2015) for time series consistency. Figure 7-3 compares the previously used Inventory
39 methodology to the revised Inventory methodology. The CH₄ emissions estimates from the previously used method
40 and the new method compare relatively well across the time series.

1 **Figure 7-2: Comparison of the Revised Inventory Methodology to EPA's GHGRP Subpart HH**
 2 **Emissions**

3
 4 Note: Emissions were back-casted from 2009 to 1990, and directly reported for 2010 to 2015.

7

1 Planned Improvements

2 The EPA will continue to investigate the annual waste disposal quantity for landfills not reporting to EPA's GHGRP
3 to develop a more precise scale-up factor to apply to the GHGRP data. The LMOP database, WBJ database, and
4 other datasets will be reviewed against the GHGRP waste disposal data. Within the GHGRP data, the previous years
5 of waste disposal reported to EPA's GHGRP by facilities will be reviewed and used in the first order decay model
6 methodology to estimate CH₄ emissions and review against the emissions estimates calculated by the new Inventory
7 methodology. EPA will also investigate options to adjust the oxidation factor from 10 percent currently used, to
8 another value such as those included in EPA's GHGRP.

10 Box 7-2: Nationwide Municipal Solid Waste Data Sources

11 Municipal solid waste generated in the United States can be managed through landfilling, recycling, composting,
12 and combustion with energy recovery. There are three main sources for nationwide solid waste management data in
13 the United States:

- 14 • The *BioCycle* and Earth Engineering Center of Columbia University's State of Garbage (SOG) in America
15 surveys [no longer published];
- 16 • The EPA's *Advancing Sustainable Materials Management* reports; and
- 17 • The Environmental Research & Education Foundation's (EREF) *Municipal Solid Waste Generation in the*
18 *United States* reports.

19 The SOG surveys and, now EREF, collect state-reported data on the amount of waste generated and the amount of
20 waste managed via different management options: landfilling, recycling, composting, and combustion. The survey
21 asks for actual tonnages instead of percentages in each waste category (e.g., residential, commercial, industrial,
22 construction and demolition, organics, tires) for each waste management option. If such a breakdown is not
23 available, the survey asks for total tons landfilled. The data are adjusted for imports and exports across state lines so
24 that the principles of mass balance are adhered to, whereby the amount of waste managed does not exceed the
25 amount of waste generated. The SOG and EREF reports present survey data aggregated to the state level.

26 The EPA *Advancing Sustainable Materials Management* reports use a materials flow methodology, which relies
27 heavily on a mass balance approach. Data are gathered from industry associations, key businesses, similar industry
28 sources, and government agencies (e.g., the Department of Commerce and the U.S. Census Bureau) and are used to
29 estimate tons of materials and products generated, recycled, or discarded nationwide. The amount of MSW
30 generated is estimated by adjusting the imports and exports of produced materials to other countries. MSW that is
31 not recycled, composted, or combusted is assumed to be landfilled. The data presented in the report are nationwide
32 totals.

33 The SOG surveys have now been replaced by the EREF reports, and are the preferred data source for estimating
34 waste generation and disposal amounts over the EPA *Sustainable Materials Management* reports in the Inventory
35 because they are considered a more objective, numbers-based analysis of solid waste management in the United
36 States. However, the EPA *Sustainable Materials Management* reports are useful when investigating waste
37 management trends at the nationwide level and for typical waste composition data, which the SOG and EREF
38 surveys do not request.

39 In this Inventory, emissions from solid waste management are presented separately by waste management option,
40 except for recycling of waste materials. Emissions from recycling are attributed to the stationary combustion of
41 fossil fuels that may be used to power on-site recycling machinery, and are presented in the stationary combustion
42 chapter in the Energy sector, although the emissions estimates are not called out separately. Emissions from solid
43 waste disposal in landfills and the composting of solid waste materials are presented in the Landfills and
44 Composting chapters in the Waste sector of this report. In the United States, almost all incineration of MSW occurs
45 at waste-to-energy (WTE) facilities or industrial facilities where useful energy is recovered, and thus emissions from
46 waste incineration are accounted for in the Incineration of Waste chapter of the Energy sector of this report.

Box 7-3: Overview of Municipal Solid Waste Management

As shown in Figure 7-4 and Figure 7-5, landfilling of MSW is currently and has been the most common waste management practice. A large portion of materials in the waste stream are recovered for recycling and composting, which is becoming an increasingly prevalent trend throughout the country. Materials that are composted and recycled would have normally been disposed of in a landfill.

Figure 7-4: Management of Municipal Solid Waste in the United States, 2014

Source: EPA (2016b).

Figure 7-5: MSW Management Trends from 1990 to 2014

Source: EPA (2016).

1 Table 7-6 presents a typical composition of waste disposed of at a typical MSW landfill in the United States over
 2 time. It is important to note that the actual composition of waste entering each landfill will vary from that presented
 3 in Table 7-6. Understanding how the waste composition changes over time, specifically for the degradable waste
 4 types, is important for estimating greenhouse gas emissions. For certain degradable waste types (i.e., paper and
 5 paperboard), the amounts discarded have decreased over time due to an increase in waste recovery, including
 6 recycling and composting (see Table 7-6 and Figure 7-6) do not reflect the impact of backyard composting on yard
 7 trimming generation and recovery estimates. The recovery of food trimmings has been consistently low. Increased
 8 recovery of degradable materials reduces the CH₄ generation potential and CH₄ emissions from landfills.

9 **Table 7-6: Materials Discarded^a in the Municipal Waste Stream by Waste Type from 1990 to**
 10 **2014 (Percent)**

Box 7-4: Description of a Modern, Managed Landfill

Modern, managed landfills are well-engineered facilities that are located, designed, operated, and monitored to ensure compliance with federal, state, and tribal regulations. Municipal solid waste (MSW) landfills must be designed to protect the environment from contaminants which may be present in the solid waste stream. Additionally, many new landfills collect and destroy landfill gas through flares or landfill gas-to-energy projects. Requirements for affected MSW landfills may include:

- Siting requirements to protect sensitive areas (e.g., airports, floodplains, wetlands, fault areas, seismic impact zones, and unstable areas);
- Design requirements for new landfills to ensure that Maximum Contaminant Levels (MCLs) will not be exceeded in the uppermost aquifer (e.g., composite liners and leachate collection systems);
- Leachate collection and removal systems;
- Operating practices (e.g., daily and intermediate cover, receipt of regulated hazardous wastes, use of landfill cover material, access options to prevent illegal dumping, use of a collection system to prevent stormwater run-on/run-off, record-keeping);
- Air monitoring requirements (explosive gases);
- Groundwater monitoring requirements;
- Closure and post-closure care requirements (e.g., final cover construction); and
- Corrective action provisions.

Specific federal regulations that affected MSW landfills must comply with include the 40 CFR Part 258 (Subtitle D of RCRA), or equivalent state regulations and the New Source Performance Standards (NSPS) 40 CFR Part 60 Subpart WWW. Additionally, state and tribal requirements may exist.⁴

7.2 Wastewater Treatment (IPCC Source Category 5D)

Wastewater treatment processes can produce anthropogenic methane (CH₄) and nitrous oxide (N₂O) emissions. Wastewater from domestic and industrial sources is treated to remove soluble organic matter, suspended solids, pathogenic organisms, and chemical contaminants.⁵ Treatment may either occur on site, most commonly through septic systems or package plants, or off site at centralized treatment systems. In the United States, approximately 19 percent of domestic wastewater is treated in septic systems or other on-site systems, while the rest is collected and treated centrally (U.S. Census Bureau 2013). Centralized wastewater treatment systems may include a variety of processes, ranging from lagooning to advanced tertiary treatment technology for removing nutrients. Some wastewater may also be treated through the use of constructed (or semi-natural) wetland systems, though it is much less common in the United States (ERG 2016). Constructed wetlands may be used as the primary method of wastewater treatment, or as a tertiary treatment step following settling and biological treatment. Constructed wetlands develop natural processes that involve vegetation, soil, and associated microbial assemblages to trap and treat incoming contaminants (IPCC 2014).

Soluble organic matter is generally removed using biological processes in which microorganisms consume the organic matter for maintenance and growth. The resulting biomass (sludge) is removed from the effluent prior to discharge to the receiving stream. Microorganisms can biodegrade soluble organic material in wastewater under aerobic or anaerobic conditions, where the latter condition produces CH₄. During collection and treatment,

⁴ For more information regarding federal MSW landfill regulations, see http://www.epa.gov/osw/nonhaz/municipal/landfill/msw_regs.htm.

⁵ Throughout the Inventory, emissions from domestic wastewater also include any commercial and industrial wastewater collected and co-treated with domestic wastewater.

wastewater may be accidentally or deliberately managed under anaerobic conditions. In addition, the sludge may be further biodegraded under aerobic or anaerobic conditions. The generation of N₂O may also result from the treatment of domestic wastewater during both nitrification and denitrification of the nitrogen (N) present, usually in the form of urea, ammonia, and proteins. These compounds are converted to nitrate (NO₃) through the aerobic process of nitrification. Denitrification occurs under anoxic conditions (without free oxygen), and involves the biological conversion of nitrate into dinitrogen gas (N₂). Nitrous oxide can be an intermediate product of both processes, but has typically been associated with denitrification. Recent research suggests that higher emissions of N₂O may in fact originate from nitrification (Ahn et al. 2010). Other more recent research suggests that N₂O may also result from other types of wastewater treatment operations (Chandran 2012).

The principal factor in determining the CH₄ generation potential of wastewater is the amount of degradable organic material in the wastewater. Common parameters used to measure the organic component of the wastewater are the biochemical oxygen demand (BOD) and chemical oxygen demand (COD). Under the same conditions, wastewater with higher COD (or BOD) concentrations will generally yield more CH₄ than wastewater with lower COD (or BOD) concentrations. BOD represents the amount of oxygen that would be required to completely consume the organic matter contained in the wastewater through aerobic decomposition processes, while COD measures the total material available for chemical oxidation (both biodegradable and non-biodegradable). The BOD value is most commonly expressed in milligrams of oxygen consumed per liter of sample during 5 days of incubation at 20 degrees C, or BOD₅. Because BOD is an aerobic parameter, it is preferable to use COD to estimate CH₄ production. The principal factor in determining the N₂O generation potential of wastewater is the amount of N in the wastewater. The variability of N in the influent to the treatment system, as well as the operating conditions of the treatment system itself, also impact the N₂O generation potential.

In 2015, CH₄ emissions from domestic wastewater treatment were 9.0 MMT CO₂ Eq. (359 kt CH₄). Emissions remained fairly steady from 1990 through 1997, but have decreased since that time due to decreasing percentages of wastewater being treated in anaerobic systems, including reduced use of on-site septic systems and central anaerobic treatment systems (EPA 1992, 1996, 2000, and 2004; U.S. Census 2013). In 2015, CH₄ emissions from industrial wastewater treatment were estimated to be 5.8 MMT CO₂ Eq. (231 kt CH₄). Industrial emission sources have generally increased across the time series through 1999 and then fluctuated up and down with production changes associated with the treatment of wastewater from the pulp and paper manufacturing, meat and poultry processing, fruit and vegetable processing, starch-based ethanol production, and petroleum refining industries. Table 7-7 and Table 7-8 provide CH₄ and N₂O emission estimates from domestic and industrial wastewater treatment.

With respect to N₂O, the United States identifies two distinct sources for N₂O emissions from domestic wastewater: emissions from centralized wastewater treatment processes, and emissions from effluent from centralized treatment systems that has been discharged into aquatic environments. The 2015 emissions of N₂O from centralized wastewater treatment processes and from effluent were estimated to be 0.3 MMT CO₂ Eq. (1.2 kt N₂O) and 4.6 MMT CO₂ Eq. (15.5 kt N₂O), respectively. Total N₂O emissions from domestic wastewater were estimated to be 5.0 MMT CO₂ Eq. (16.7 kt N₂O). Nitrous oxide emissions from wastewater treatment processes gradually increased across the time series as a result of increasing U.S. population and protein consumption. N₂O emissions are not estimated from industrial wastewater treatment because there is no IPCC methodology provided or industrial wastewater emission factors available.

Table 7-7: CH₄ and N₂O Emissions from Domestic and Industrial Wastewater Treatment (MMT CO₂ Eq.)

Activity	1990	2005	2011	2012	2013	2014	2015

Methodology

Domestic Wastewater CH₄ Emission Estimates

Domestic wastewater CH₄ emissions originate from both septic systems and from centralized treatment systems, such as publicly owned treatment works (POTWs). Within these centralized systems, CH₄ emissions can arise from aerobic systems that are not well managed or that are designed to have periods of anaerobic activity (e.g., constructed wetlands and facultative lagoons), anaerobic systems (anaerobic lagoons and anaerobic reactors), and from anaerobic digesters when the captured biogas is not completely combusted. The methodological equations are:

$$\begin{aligned} \text{Emissions from Septic Systems} &= A \\ &= \text{US}_{\text{POP}} \times (\% \text{ onsite}) \times (\text{EF}_{\text{SEPTIC}}) \times 1/10^9 \times 365.25 \end{aligned}$$

$$\begin{aligned} &\text{Emissions from Centrally Treated Aerobic Systems (other than Constructed Wetlands)} + \text{Emissions from} \\ &\text{Centrally Treated Aerobic Systems (Constructed Wetlands Only)} + \text{Emissions from Centrally Treated Aerobic} \\ &\text{Systems (Constructed Wetlands used as Tertiary Treatment)} = B \end{aligned}$$

where,

$$\begin{aligned} &\text{Emissions from Centrally Treated Aerobic Systems (other than Constructed Wetlands)} \\ &= [(\% \text{ collected}) \times (\text{total BOD}_5 \text{ produced}) \times (\% \text{ aerobic}_{\text{OTCW}}) \times (\% \text{ aerobic w/out primary}) + (\% \text{ collected}) \times \\ &(\text{total BOD}_5 \text{ produced}) \times (\% \text{ aerobic}_{\text{OTCW}}) \times (\% \text{ aerobic w/primary}) \times (1 - \% \text{ BOD removed in prim. treat.})] \times \\ &(\% \text{ operations not well managed}) \times (B_o) \times (\text{MCF-aerobic_not_well_man}) \end{aligned}$$

$$\begin{aligned} &\text{Emissions from Centrally Treated Aerobic Systems (Constructed Wetlands Only)} \\ &= [(\% \text{ collected}) \times (\text{total BOD}_5 \text{ produced}) \times (\% \text{ aerobic}_{\text{CW}})] \times (B_o) \times (\text{MCF-constructed wetlands}) \end{aligned}$$

$$\begin{aligned} &\text{Emissions from Centrally Treated Aerobic Systems (Constructed Wetlands used as Tertiary Treatment)} \\ &= [(\text{POTW_flow_CW}) \times (\text{BOD}_{\text{CW,INF}}) \times 3.79] \times 1/10^6 \times 365.25 \end{aligned}$$

$$\begin{aligned} &\text{Emissions from Centrally Treated Anaerobic Systems} = C \\ &= \{[(\% \text{ collected}) \times (\text{total BOD}_5 \text{ produced}) \times (\% \text{ anaerobic}) \times (\% \text{ anaerobic w/out primary})] + [(\% \\ &\text{collected}) \times (\text{total BOD}_5 \text{ produced}) \times (\% \text{ anaerobic}) \times (\% \text{ anaerobic w/primary}) \times (1 - \% \text{ BOD removed in} \\ &\text{prim. treat.})]\} \times (B_o) \times (\text{MCF-anaerobic}) \end{aligned}$$

$$\begin{aligned} &\text{Emissions from Anaerobic Digesters} = D \\ &= [(\text{POTW_flow_AD}) \times (\text{digester gas}) / (\text{per capita flow})] \times \text{conversion to m}^3 \times (\text{FRAC_CH}_4) \times 365.25 \times \\ &(\text{density of CH}_4) \times (1 - \text{DE}) \times 1/10^9 \end{aligned}$$

$$\text{Total Domestic CH}_4 \text{ Emissions from Wastewater (kt)} = A + B + C + D$$

where,

US _{POP}	= U.S. population
% onsite	= Flow to septic systems / total flow
% collected	= Flow to POTWs / total flow

1	% aerobic _{OTCW}	= Flow to aerobic systems, other than wetlands only / total flow to POTWs
2		
3	% aerobic _{CW}	= Flow to aerobic systems, constructed wetlands used as sole treatment / total flow to POTWs
4		
5	% anaerobic	= Flow to anaerobic systems / total flow to POTWs
6	% aerobic w/out primary	= Percent of aerobic systems that do not employ primary treatment
7	% aerobic w/primary	= Percent of aerobic systems that employ primary treatment
8	% BOD removed in prim. treat.	= Percent of BOD removed in primary treatment
9	% operations not well managed	= Percent of aerobic systems that are not well managed and in which some anaerobic degradation occurs
10		
11	% anaerobic w/out primary	= Percent of anaerobic systems that do not employ primary treatment
12	% anaerobic w/primary	= Percent of anaerobic systems that employ primary treatment
13	EF _{SEPTIC}	= Methane emission factor – septic systems
14	Total BOD ₅ produced	= kg BOD/capita/day × U.S. population × 365.25 days/yr
15	BOD _{CW,INF}	= BOD concentration in wastewater entering the constructed wetland
16	B _o	= Maximum CH ₄ -producing capacity for domestic wastewater
17	1/10 ⁶	= Conversion factor, kg to kt
18	365.25	= Days in a year
19	3.79	= Conversion factor, liters to gallons
20	MCF-aerobic_not_well_man.	= CH ₄ correction factor for aerobic systems that are not well managed
21	MCF-anaerobic	= CH ₄ correction factor for anaerobic systems
22	MCF-constructed wetlands	= CH ₄ correction factor for surface flow constructed wetlands
23	DE	= CH ₄ destruction efficiency from flaring or burning in engine
24	POTW_flow_CW	= Wastewater flow to POTWs that use constructed wetlands as tertiary treatment (MGD)
25		
26	POTW_flow_AD	= Wastewater influent flow to POTWs that have anaerobic digesters (MGD)
27		
28	digester gas	= Cubic feet of digester gas produced per person per day
29	100	= Wastewater flow to POTW (gallons/person/day)
30	0.0283	= Conversion factor, ft ³ to m ³
31	FRAC_CH ₄	= Proportion of CH ₄ in biogas
32	662	= Density of CH ₄ (g CH ₄ /m ³ CH ₄)
33	1/10 ⁹	= Conversion factor, g to kt

34 Emissions from Septic Systems:

35 Methane emissions from septic systems were estimated by multiplying the U.S. population by the percent of
36 wastewater treated in septic systems (about 19 percent) and an emission factor (10.7 g CH₄/capita/day) (Leverenz et
37 al. 2000), and then converting the result to kt/year. U.S. population data were taken from the U.S. Census Bureau
38 International Database (U.S. Census 2016) and include the populations of the United States, American Samoa,
39 Guam, Northern Mariana Islands, Puerto Rico, and the Virgin Islands. Table 7-9 presents U.S. population for 1990
40 through 2015.

41 Emissions from Centrally Treated Aerobic and Anaerobic Systems:

42 Methane emissions from POTWs were estimated by multiplying the total BOD₅ produced in the United States by the
43 percent of wastewater treated centrally (about 81 percent) (EPA 1992, 1996, 2000, 2004), the relative percentage of
44 wastewater treated by aerobic and anaerobic systems (other than constructed wetlands), the relative percentage of
45 wastewater facilities with primary treatment, the percentage of BOD₅ treated after primary treatment (67.5 percent,
46 32.5 percent removed in primary treatment) (Metcalf & Eddy 2003), the maximum CH₄-producing capacity of
47 domestic wastewater (B_o, 0.6 kg CH₄/kg BOD) (IPCC 2006), and the relative methane conversion factors (MCF) for
48 well-managed aerobic (zero) (IPCC 2006), not well managed aerobic (0.3,) (IPCC 2006), and anaerobic (0.8) (IPCC
49 2006) systems.

50 Table 7-9 presents total BOD₅ produced for 1990 through 2015. The proportions of domestic wastewater treated
51 onsite versus at centralized treatment plants were based on data from the 1989, 1991, 1993, 1995, 1997, 1999, 2001,
52 2003, 2005, 2007, 2009, 2011, and 2013 *American Housing Surveys* conducted by the U.S. Census Bureau (U.S.
53 Census 2013), with data for intervening years obtained by linear interpolation and data for 2014 and 2015 were

1 forecasted using 1990 to 2013 and 1990 to 2014 data, respectively. The percent of wastewater flow to aerobic and
 2 anaerobic systems, the percent of aerobic and anaerobic systems that do and do not employ primary treatment, and
 3 the wastewater flow to POTWs that have anaerobic digesters were obtained from the 1992, 1996, 2000, and 2004
 4 *Clean Watersheds Needs Survey* (EPA 1992, 1996, 2000, and 2004). Data for intervening years were obtained by
 5 linear interpolation and the years 2004 through 2014 were forecasted from the rest of the time series. The percent of
 6 wastewater flow to aerobic systems that use only constructed wetlands and wastewater flow to POTWs that use
 7 constructed wetlands as tertiary treatment were obtained from the 1992, 1996, 2000, 2004, 2008, and 2012 *Clean*
 8 *Watersheds Needs Survey* (EPA 1992, 1996, 2000, 2004, 2008b, and 2012). Data for intervening years were
 9 obtained by linear interpolation and the years 2013 through 2015 were forecasted from the rest of the time series.
 10 The BOD₅ production rate (0.09 kg/capita/day) and the percent BOD₅ removed by primary treatment for domestic
 11 wastewater were obtained from Metcalf & Eddy (2003). The B₀ value, as well as the MCFs for anaerobic and
 12 aerobic not well managed centralized treatment systems, were taken from IPCC (2006), while the CH₄ emission
 13 factor used for septic systems was taken from Leverenz et al. (2010).

14 For constructed wetlands, an MCF of 0.4 was used, which is the IPCC suggested MCF for surface flow wetlands.
 15 This is the most conservative factor for constructed wetlands and was recommended by IPCC (2014) when the type
 16 of constructed wetland is not known. A BOD concentration of 30 mg/L was used for wastewater entering
 17 constructed wetlands used as tertiary treatment based on United States secondary treatment standards for POTWs.
 18 These standards are based on plants generally utilizing simple settling and biological treatment (EPA 2013).

19 All aerobic systems are assumed to be well-managed as there are currently no data available to quantify the number
 20 of systems that are not well-managed. In addition, methane emissions were calculated for systems that treat
 21 wastewater with constructed wetlands and systems that use constructed wetlands as tertiary treatment; however,
 22 constructed wetlands are a relatively small portion of wastewater treated centrally (<0.1 percent). Methane
 23 emissions were estimated using the MCF for surface flow constructed wetlands (0.4). A BOD₅ concentration
 24 consistent with secondary treatment standards for POTWs in the United States (30 mg/L) (EPA 2013) was used to
 25 account for emissions from constructed wetlands used as tertiary treatment. Methane emissions from anaerobic
 26 digesters were estimated by multiplying the amount of biogas generated by wastewater sludge treated in anaerobic
 27 digesters by the proportion of CH₄ in digester biogas (0.65), the density of CH₄ (662 g CH₄/m³ CH₄) (EPA 1993a),
 28 and the destruction efficiency associated with burning the biogas in an energy/thermal device (0.99 for enclosed
 29 flares).

30 Table 7-10 presents domestic wastewater CH₄ emissions for both septic and centralized systems in 2015.

31 **Emissions from Anaerobic Digesters:**

32 Total CH₄ emissions from anaerobic digesters were estimated by multiplying the wastewater influent flow to
 33 POTWs with anaerobic digesters, the cubic feet of digester gas generated per person per day, the fraction of CH₄ in
 34 biogas, the density of CH₄, one minus the destruction efficiency from flaring or burning in engine and then
 35 converting the results to kt/year.

36 The CH₄ destruction efficiency for methane recovered from sludge digestion operations, 99 percent, was selected
 37 based on the range of efficiencies (98 to 100 percent) recommended for flares in *AP-42 Compilation of Air Pollutant*
 38 *Emission Factors*, Chapter 2.4 (EPA 1998), efficiencies used to establish New Source Performance Standards
 39 (NSPS) for landfills, along with data from CAR (2011), Sullivan (2007), Sullivan (2010), and UNFCCC (2012). The
 40 cubic feet of digester gas produced per person per day (1.0 ft³/person/day) and the proportion of CH₄ in biogas
 41 (0.65) come from Metcalf & Eddy (2014). The wastewater flow to a POTW (100 gal/person/day) was taken from
 42 the Great Lakes-Upper Mississippi River Board of State and Provincial Public Health and Environmental Managers,
 43 *Recommended Standards for Wastewater Facilities (Ten-State Standards)* (2004).

44 **Table 7-9: U.S. Population (Millions) and Domestic Wastewater BOD₅ Produced (kt)**

Year	Population	BOD ₅
1990	253	8,333
2005	300	9,853
2011	316	10,381
2012	318	10,459

Anaerobic Digesters	0.2	2.3%
Total	9.0	100%

Note: Totals may not sum due to independent rounding.

3 Industrial Wastewater CH₄ Emission Estimates

4 Methane emission estimates from industrial wastewater were developed according to the methodology described in
5 IPCC (2006). Industry categories that are likely to produce significant CH₄ emissions from wastewater treatment
6 were identified and included in the Inventory. The main criteria used to identify these industries are whether they
7 generate high volumes of wastewater, whether there is a high organic wastewater load, and whether the wastewater
8 is treated using methods that result in CH₄ emissions. The top five industries that meet these criteria are pulp and
9 paper manufacturing; meat and poultry processing; vegetables, fruits, and juices processing; starch-based ethanol
10 production; and petroleum refining. Wastewater treatment emissions for these sectors for 2015 are displayed in
11 Table 7-11 below. Table 7-12 contains production data for these industries.

12 **Table 7-11: Industrial Wastewater CH₄ Emissions by Sector (2015, MMT CO₂ Eq. and**
13 **Percent)**

	CH ₄ Emissions (MMT CO ₂ Eq.)	% of Industrial Wastewater CH ₄
Meat & Poultry	4.4	76%
Pulp & Paper	1.0	17%
Fruit & Vegetables	0.1	3%
Petroleum Refineries	0.1	2%
Ethanol Refineries	0.1	2%
Total	5.8	100%

Note: Totals may not sum due to independent rounding.

14 **Table 7-12: U.S. Pulp and Paper, Meat, Poultry, Vegetables, Fruits and Juices, Ethanol, and**
15 **Petroleum Refining Production (MMT)**

Year	Pulp and Paper ^a	Meat (Live Weight Killed)	Poultry (Live Weight Killed)	Vegetables, Fruits and Juices	Ethanol	Petroleum Refining
1990	128.9	27.3	14.6	38.7	2.5	702.4
2005	138.5	31.4	25.1	42.9	11.7	818.6
2011	126.1	33.8	26.2	44.3	41.6	858.8

2012	124.4	33.8	26.1	45.6	39.5	856.1
2013	122.8	33.6	26.5	45.1	39.7	878.7
2014	120.9	32.2	26.9	45.8	42.8	903.9
2015	127.1	32.8	27.7	44.8	44.2	914.9

^a Pulp and paper production is the sum of woodpulp production plus paper and paperboard production.

Sources: Lockwood-Post (2002); FAO (2016); USDA (2016a); Cooper (2016); EIA (2016).

1 Methane emissions from these categories were estimated by multiplying the annual product output by the average
 2 outflow, the organics loading (in COD) in the outflow, the maximum CH₄ producing potential of industrial
 3 wastewater (B_o), and the percentage of organic loading assumed to degrade anaerobically in a given treatment
 4 system (MCF). Ratios of BOD:COD in various industrial wastewaters were obtained from EPA (1997a) and used to
 5 estimate COD loadings. The B_o value used for all industries is the IPCC default value of 0.25 kg CH₄/kg COD
 6 (IPCC 2006).

7 For each industry, the percent of plants in the industry that treat wastewater on site, the percent of plants that have a
 8 primary treatment step prior to biological treatment, and the percent of plants that treat wastewater anaerobically
 9 were defined. The percent of wastewater treated anaerobically onsite (TA) was estimated for both primary treatment
 10 (%TA_p) and secondary treatment (%TA_s). For plants that have primary treatment in place, an estimate of COD that
 11 is removed prior to wastewater treatment in the anaerobic treatment units was incorporated. The values used in the
 12 %TA calculations are presented in Table 7-13 below.

13 The methodological equations are:

$$14 \quad \text{CH}_4 (\text{industrial wastewater}) = [P \times W \times \text{COD} \times \%TA_p \times B_o \times \text{MCF}] + [P \times W \times \text{COD} \times \%TA_s \times B_o \times \text{MCF}]$$

$$15 \quad \%TA_p = [\%Plants_o \times \%WW_{a,p} \times \%COD_p]$$

$$16 \quad \%TA_s = [\%Plants_a \times \%WW_{a,s} \times \%COD_s] + [\%Plants_t \times \%WW_{a,t} \times \%COD_s]$$

17 where,

18 CH₄ (industrial wastewater) = Total CH₄ emissions from industrial wastewater (kg/year)

19 P = Industry output (metric tons/year)

20 W = Wastewater generated (m³/metric ton of product)

21 COD = Organics loading in wastewater (kg/m³)

22 %TA_p = Percent of wastewater treated anaerobically on site in primary treatment

23 %TA_s = Percent of wastewater treated anaerobically on site in secondary treatment

24 %Plants_o = Percent of plants with onsite treatment

25 %WW_{a,p} = Percent of wastewater treated anaerobically in primary treatment

26 %COD_p = Percent of COD entering primary treatment

27 %Plants_a = Percent of plants with anaerobic secondary treatment

28 %Plants_t = Percent of plants with other secondary treatment

29 %WW_{a,s} = Percent of wastewater treated anaerobically in anaerobic secondary treatment

30 %WW_{a,t} = Percent of wastewater treated anaerobically in other secondary treatment

31 %COD_s = Percent of COD entering secondary treatment

32 B_o = Maximum CH₄ producing potential of industrial wastewater (kg CH₄/kg
 33 COD)

34 MCF = CH₄ correction factor, indicating the extent to which the organic content
 35 (measured as COD) degrades anaerobically

36 Alternate methodological equations for calculating %TA were used for secondary treatment in the pulp and paper
 37 industry to account for aerobic systems with anaerobic portions. These equations are:

$$38 \quad \%TA_a = [\%Plants_a \times \%WW_{a,s} \times \%COD_s] + [\%Plants_{s,t} \times \%WW_{a,t} \times \%COD_s]$$

$$39 \quad \%TA_{a,t} = [\%Plants_{a,t} \times \%WW_{a,s} \times \%COD_s]$$

40 where,

41 %TA_a = Percent of wastewater treated anaerobically on site in secondary treatment

42 %TA_{a,t} = Percent of wastewater treated in aerobic systems with anaerobic portions on
 43 site in secondary treatment

- 1 %Plants_a = Percent of plants with anaerobic secondary treatment
2 %Plants_{a,t} = Percent of plants with partially anaerobic secondary treatment
3 %WW_{a,s} = Percent of wastewater treated anaerobically in anaerobic secondary treatment
4 %WW_{a,t} = Percent of wastewater treated anaerobically in other secondary treatment
5 %COD_s = Percent of COD entering secondary treatment

6 As described below, the values presented in Table 7-13 were used in the emission calculations and are described in
7 detail in ERG (2008), ERG (2013a), and ERG (2013b).

8 **Table 7-13: Variables Used to Calculate Percent Wastewater Treated Anaerobically by**
9 **Industry (Percent)**

Variable	Industry						
	Pulp and Paper	Meat Processing	Poultry Processing	Fruit/Vegetable Processing	Ethanol Production – Wet Mill	Ethanol Production – Dry Mill	Petroleum Refining
%TA _p	0	0	0	0	0	0	0
%TA _s	0	33	25	4.2	33.3	75	23.6
%TA _a	2.2	0	0	0	0	0	0
%TA _{a,t}	11.8	0	0	0	0	0	0
%Plants _{so}	0	100	100	11	100	100	100
%Plants _a	5	33	25	5.5	33.3	75	23.6
%Plants _{a,t}	28	0	0	0	0	0	0
%Plants _t	35	67	75	5.5	66.7	25	0
%WW _{a,p}	0	0	0	0	0	0	0
%WW _{a,s}	100	100	100	100	100	100	100
%WW _{a,t}	0	0	0	0	0	0	0
%COD _p	100	100	100	100	100	100	100
%COD _s	42	100	100	77	100	100	100

Note: Due to differences in data availability and methodology, zero values in the table may be used for calculation purposes only.

Sources: ERG (2008); ERG (2013a); and ERG (2013b).

10 *Pulp and Paper.* Wastewater treatment for the pulp and paper industry typically includes neutralization, screening,
11 sedimentation, and flotation/hydrocycloning to remove solids (World Bank 1999; Nemerow and Dasgupta 1991).
12 Secondary treatment (storage, settling, and biological treatment) mainly consists of lagooning. In determining the
13 percent that degrades anaerobically, both primary and secondary treatment were considered. In the United States,
14 primary treatment is focused on solids removal, equalization, neutralization, and color reduction (EPA 1993b). The
15 vast majority of pulp and paper mills with on-site treatment systems use mechanical clarifiers to remove suspended
16 solids from the wastewater. About 10 percent of pulp and paper mills with treatment systems use settling ponds for
17 primary treatment and these are more likely to be located at mills that do not perform secondary treatment (EPA
18 1993b). However, because the vast majority of primary treatment operations at U.S. pulp and paper mills use
19 mechanical clarifiers, and less than 10 percent of pulp and paper wastewater is managed in primary settling ponds
20 that are not expected to have anaerobic conditions, negligible emissions are assumed to occur during primary
21 treatment.

22 Approximately 42 percent of the BOD passes on to secondary treatment, which consists of activated sludge, aerated
23 stabilization basins, or non-aerated stabilization basins. Based on EPA's *OAQPS Pulp and Paper Sector Survey, 5.3*
24 percent of pulp and paper mills reported using anaerobic secondary treatment for wastewater and/or pulp
25 condensates (ERG 2013a). Twenty-eight percent of mills also reported the use of quiescent settling ponds. Using
26 engineering judgment, these systems were determined to be aerobic with possible anaerobic portions. For the truly
27 anaerobic systems, an MCF of 0.8 is used, as these are typically deep stabilization basins. For the partially anaerobic
28 systems, an MCF of 0.2 is used, which is the IPCC suggested MCF for shallow lagoons.

29 A time series of CH₄ emissions for 1990 through 2001 was developed based on production figures reported in the
30 Lockwood-Post Directory (Lockwood-Post 2002). Data from the Food and Agricultural Organization of the United
31 Nations (FAO) database FAOSTAT were used for 2002 through 2015 (FAO 2016). The overall wastewater outflow
32 varies based on a time series outlined in ERG (2013a) to reflect historical and current industry wastewater flow, and

1 the average BOD concentrations in raw wastewater was estimated to be 0.4 gram BOD/liter (EPA 1997b; EPA
 2 1993b; World Bank 1999). The COD:BOD ratio used to convert the organic loading to COD for pulp and paper
 3 mills was 2 (EPA 1997a).

4 *Meat and Poultry Processing.* The meat and poultry processing industry makes extensive use of anaerobic lagoons
 5 in sequence with screening, fat traps, and dissolved air flotation when treating wastewater on site. About 33 percent
 6 of meat processing operations (EPA 2002) and 25 percent of poultry processing operations (U.S. Poultry 2006)
 7 perform on-site treatment in anaerobic lagoons. The IPCC default B_0 of 0.25 kg CH_4 /kg COD and default MCF of
 8 0.8 for anaerobic lagoons were used to estimate the CH_4 produced from these on-site treatment systems. Production
 9 data, in carcass weight and live weight killed for the meat and poultry industry, were obtained from the USDA
 10 *Agricultural Statistics Database and the Agricultural Statistics Annual Reports* (USDA 2016a). Data collected by
 11 EPA’s Office of Water provided estimates for wastewater flows into anaerobic lagoons: 5.3 and 12.5 m³/metric ton
 12 for meat and poultry production (live weight killed), respectively (EPA 2002). The loadings are 2.8 and 1.5 g
 13 BOD/liter for meat and poultry, respectively. The COD:BOD ratio used to convert the organic loading to COD for
 14 both meat and poultry facilities was 3 (EPA 1997a).

15 *Vegetables, Fruits, and Juices Processing.* Treatment of wastewater from fruits, vegetables, and juices processing
 16 includes screening, coagulation/settling, and biological treatment (lagooning). The flows are frequently seasonal,
 17 and robust treatment systems are preferred for on-site treatment. Effluent is suitable for discharge to the sewer. This
 18 industry is likely to use lagoons intended for aerobic operation, but the large seasonal loadings may develop limited
 19 anaerobic zones. In addition, some anaerobic lagoons may also be used (Nemerow and Dasgupta 1991).
 20 Consequently, 4.2 percent of these wastewater organics are assumed to degrade anaerobically. The IPCC default B_0
 21 of 0.25 kg CH_4 /kg COD and default MCF of 0.8 for anaerobic treatment were used to estimate the CH_4 produced
 22 from these on-site treatment systems. The USDA National Agricultural Statistics Service (USDA 2016a) provided
 23 production data for potatoes, other vegetables, citrus fruit, non-citrus fruit, and grapes processed for wine. Outflow
 24 and BOD data, presented in Table 7-14, were obtained from EPA (1974) for potato, citrus fruit, and apple
 25 processing, and from EPA (1975) for all other commodities. The COD:BOD ratio used to convert the organic
 26 loading to COD for all fruit, vegetable, and juice facilities was 1.5 (EPA 1997a).

27 **Table 7-14: Wastewater Flow (m³/ton) and BOD Production (g/L) for U.S. Vegetables,**
 28 **Fruits, and Juices Production**

Commodity	Wastewater Outflow (m ³ /ton)	BOD (g/L)
Vegetables		
Potatoes	10.27	1.765
Other Vegetables	8.60	0.784
Fruit		
Apples	3.66	1.371
Citrus Fruits	10.11	0.317
Non-citrus Fruits	12.42	1.204
Grapes (for wine)	2.78	1.831

Sources: EPA (1974); EPA (1975).

29 *Ethanol Production.* Ethanol, or ethyl alcohol, is produced primarily for use as a fuel component, but is also used in
 30 industrial applications and in the manufacture of beverage alcohol. Ethanol can be produced from the fermentation
 31 of sugar-based feedstocks (e.g., molasses and beets), starch- or grain-based feedstocks (e.g., corn, sorghum, and
 32 beverage waste), and cellulosic biomass feedstocks (e.g., agricultural wastes, wood, and bagasse). Ethanol can also
 33 be produced synthetically from ethylene or hydrogen and carbon monoxide. However, synthetic ethanol comprises
 34 only about 2 percent of ethanol production, and although the U.S. Department of Energy (DOE) predicts cellulosic
 35 ethanol to greatly increase in the coming years, currently it is only in an experimental stage in the United States.
 36 Currently, ethanol is mostly made from sugar and starch crops, but with advances in technology, cellulosic biomass
 37 is increasingly used as ethanol feedstock (DOE 2013).

38 Ethanol is produced from corn (or other starch-based feedstocks) primarily by two methods: wet milling and dry
 39 milling. Historically, the majority of ethanol was produced by the wet milling process, but now the majority is
 40 produced by the dry milling process. The dry milling process is cheaper to implement, and has become more
 41 efficient in recent years (Rendleman and Shapouri 2007). The wastewater generated at ethanol production facilities

1 is handled in a variety of ways. Dry milling facilities often combine the resulting evaporator condensate with other
 2 process wastewaters, such as equipment wash water, scrubber water, and boiler blowdown and anaerobically treat
 3 this wastewater using various types of digesters. Wet milling facilities often treat their steepwater condensate in
 4 anaerobic systems followed by aerobic polishing systems. Wet milling facilities may treat the stillage (or processed
 5 stillage) from the ethanol fermentation/distillation process separately or together with steepwater and/or wash water.
 6 Methane generated in anaerobic digesters is commonly collected and either flared or used as fuel in the ethanol
 7 production process (ERG 2006).

8 Available information was compiled from the industry on wastewater generation rates, which ranged from 1.25
 9 gallons per gallon ethanol produced (for dry milling) to 10 gallons per gallon ethanol produced (for wet milling)
 10 (Ruocco 2006a; Ruocco 2006b; Merrick 1998; Donovan 1996; NRBP 2001). COD concentrations were also found
 11 to be about 3 g/L (Ruocco 2006a; Merrick 1998; White and Johnson 2003). One hundred percent of plants were
 12 estimated to have onsite wastewater treatment, and the variables used to calculate percent wastewater treated
 13 anaerobically are presented in Table 7-13. A default MCF of 0.8 for anaerobic treatment was used to estimate the
 14 CH₄ produced from these on-site treatment systems. The amount of CH₄ recovered through the use of
 15 biomethanators was estimated, and a 99 percent destruction efficiency was used. Biomethanators are anaerobic
 16 reactors that use microorganisms under anaerobic conditions to reduce COD and organic acids and recover biogas
 17 from wastewater (ERG 2006). Methane emissions were then estimated as follows:

$$\begin{aligned}
 \text{Methane} = & [\text{Production} \times \text{Flow} \times \text{COD} \times 3.785 \times ([\% \text{Plants}_o \times \% \text{WW}_{a,p} \times \% \text{COD}_p] + [\% \text{Plants}_a \times \% \text{WW}_{a,s} \times \\
 & \% \text{COD}_s] + [\% \text{Plants}_t \times \% \text{WW}_{a,t} \times \% \text{COD}_s]) \times B_o \times \text{MCF} \times \% \text{Not Recovered}] + [\text{Production} \times \text{Flow} \times 3.785 \times \\
 & \text{COD} \times ([\% \text{Plants}_o \times \% \text{WW}_{a,p} \times \% \text{COD}_p] + [\% \text{Plants}_a \times \% \text{WW}_{a,s} \times \% \text{COD}_s] + [\% \text{Plants}_t \times \% \text{WW}_{a,t} \times \% \text{COD}_s]) \\
 & \times B_o \times \text{MCF} \times (\% \text{Recovered}) \times (1 - \text{DE})] \times 1/10^9
 \end{aligned}$$

23 where,

24	Production	= Gallons ethanol produced (wet milling or dry milling)
25	Flow	= Gallons wastewater generated per gallon ethanol produced
26	COD	= COD concentration in influent (g/l)
27	3.785	= Conversion factor, gallons to liters
28	%Plants _o	= Percent of plants with onsite treatment
29	%WW _{a,p}	= Percent of wastewater treated anaerobically in primary treatment
30	%COD _p	= Percent of COD entering primary treatment
31	%Plants _a	= Percent of plants with anaerobic secondary treatment
32	%Plants _t	= Percent of plants with other secondary treatment
33	%WW _{a,s}	= Percent of wastewater treated anaerobically in anaerobic secondary treatment
34	%WW _{a,t}	= Percent of wastewater treated anaerobically in other secondary treatment
35	%COD _s	= Percent of COD entering secondary treatment
36	B _o	= Maximum methane producing capacity (g CH ₄ /g COD)
37	MCF	= Methane conversion factor
38	% Recovered	= Percent of wastewater treated in system with emission recovery
39	% Not Recovered	= 1 - percent of wastewater treated in system with emission recovery
40	DE	= Destruction efficiency of recovery system
41	1/10 ⁹	= Conversion factor, g to kt

42 A time series of CH₄ emissions for 1990 through 2015 was developed based on production data from the Renewable
 43 Fuels Association (Cooper 2016).

44 *Petroleum Refining.* Petroleum refining wastewater treatment operations have the potential to produce CH₄
 45 emissions from anaerobic wastewater treatment. EPA's Office of Air and Radiation performed an Information
 46 Collection Request (ICR) for petroleum refineries in 2011.⁶ Of the responding facilities, 23.6 percent reported using
 47 non-aerated surface impoundments or other biological treatment units, both of which have the potential to lead to
 48 anaerobic conditions (ERG 2013b). In addition, the wastewater generation rate was determined to be 26.4 gallons

⁶ See <<https://refineryicr.rti.org/>>.

1 per barrel of finished product (ERG 2013b). An average COD value in the wastewater was estimated at 0.45 kg/m³
2 (Benyahia et al. 2006). A default MCF of 0.3 was used for partially aerobic systems.

3 The equation used to calculate CH₄ generation at petroleum refining wastewater treatment systems is presented
4 below:

$$5 \quad \text{Methane} = \text{Flow} \times \text{COD} \times \%TA \times B_o \times \text{MCF}$$

6 where,

7	Flow	= Annual flow treated through anaerobic treatment system (m ³ /year)
8	COD	= COD loading in wastewater entering anaerobic treatment system (kg/m ³)
9	%TA	= Percent of wastewater treated anaerobically on site
10	B _o	= Maximum methane producing potential of industrial wastewater (kg CH ₄ /kg COD)
11	MCF	= Methane conversion factor

12 A time series of CH₄ emissions for 1990 through 2015 was developed based on production data from the Energy
13 Information Administration (EIA 2016).

14 Domestic Wastewater N₂O Emission Estimates

15 Nitrous oxide emissions from domestic wastewater (wastewater treatment) were estimated using the IPCC (2006)
16 methodology and supplemented with IPCC (2014) methodology to include constructed wetland emissions, including
17 calculations that take into account N removal with sewage sludge, non-consumption and industrial/commercial
18 wastewater N, and emissions from advanced and constructed wetlands at centralized wastewater treatment plants:

- 19 • In the United States, a certain amount of N is removed with sewage sludge, which is applied to land,
20 incinerated, or landfilled (N_{SLUDGE}). The N discharged into aquatic environments as effluent is reduced to
21 account for the sewage sludge application.
- 22 • The IPCC methodology uses annual, per capita protein consumption (kg protein/person-year). For this
23 Inventory, the amount of protein available to be consumed is estimated based on per capita annual food
24 availability data and its protein content, and then that data is adjusted using a factor to account for the fraction
25 of protein actually consumed.
- 26 • Small amounts of gaseous nitrogen oxides are formed as byproducts in the conversion of nitrate to N gas in
27 anoxic biological treatment systems. Approximately 7 g N₂O is generated per capita per year if wastewater
28 treatment includes intentional nitrification and denitrification (Scheehle and Doorn 2001). Analysis of the use
29 of treatment systems in the United States that include denitrification has shown a significant increase in the
30 time period between 2004 and 2012, from serving populations totaling 2.4 million people to 21.3 million
31 people (EPA 2004 and EPA 2012). This is consistent with efforts throughout the United States to improve
32 nutrient removal at centralized treatment systems in response to specific water quality concerns. Based on an
33 emission factor of 7 g per capita per year, approximately 21.2 metric tons of additional N₂O may have been
34 emitted via denitrification in 2004, while about 186 metric tons may have been emitted via denitrification in
35 both 2008 and 2012. Similar analyses were completed for each year in the Inventory using data from CWNS
36 on the amount of wastewater in centralized systems treated in denitrification units. Plants without intentional
37 nitrification or denitrification are assumed to generate 3.2 g N₂O per capita per year.
- 38 • Constructed wetlands may be used as the sole treatment unit at a centralized wastewater treatment plant or
39 may serve as tertiary treatment after simple settling and biological treatment. Emissions from all constructed
40 wetland systems were included in the estimates of emissions from centralized wastewater treatment plant
41 processes and effluent from these plants. The emission factor of 0.0013 kg N₂O-N/kg N produced for
42 constructed wetlands is from IPCC (2014).
- 43 • N₂O emissions from wastewater treatment plants are estimated, and as such, the N associated with these
44 emissions is subtracted from the amount of N estimated to be discharged into aquatic environments as
45 effluent, consistent with the IPCC methodology.

46 Nitrous oxide emissions from domestic wastewater were estimated using the following methodology:

$$47 \quad N_2O_{TOTAL} = N_2O_{PLANT} + N_2O_{EFFLUENT}$$

$$\begin{aligned}
1 \quad & N_2O_{PLANT} = N_2O_{NIT/DENIT} + N_2O_{WOUT\ NIT/DENIT} + N_2O_{CW\ ONLY} + N_2O_{CW\ TERTIARY} \\
2 \quad & N_2O_{NIT/DENIT} = [(US_{POPND}) \times EF_2 \times F_{IND-COM}] \times 1/10^9 \\
3 \quad & N_2O_{WOUT\ NIT/DENIT} = \{[(US_{POP} \times WWTP) - US_{POPND} - US_{POPCW}] \times 10^6 \times F_{IND-COM} \times EF_1\} \times 1/10^9 \\
4 \quad & N_2O_{CW\ ONLY} = \{[(US_{POPCW} \times 10^6 \times Protein \times F_{NPR} \times F_{NON-CON} \times F_{IND-COM}) \times EF_4] \times 44/28\} \times 1/10^6 \\
5 \quad & N_2O_{CW\ TERTIARY} = \{[(N_{CW,INF} \times POTW_flow_CW \times 3.79 \times 365.25) \times EF_4] \times 44/28\} \times 1/10^6 \\
6 \quad & N_2O_{EFFLUENT} = [(US_{POP} \times WWTP \times Protein \times F_{NPR} \times F_{NON-CON} \times F_{IND-COM}) - N_{SLUDGE} - (N_2O_{PLANT} \times 10^6 \times 28/44)] \times \\
7 \quad & EF_3 \times 44/28 \times 1/10^6
\end{aligned}$$

8 where,

9	N_2O_{TOTAL}	= Annual emissions of N_2O (kt)
10	N_2O_{PLANT}	= N_2O emissions from centralized wastewater treatment plants (kt)
11	$N_2O_{NIT/DENIT}$	= N_2O emissions from centralized wastewater treatment plants with nitrification/denitrification (kt)
12		
13	$N_2O_{WOUT\ NIT/DENIT}$	= N_2O emissions from centralized wastewater treatment plants without nitrification/denitrification (kt)
14		
15	$N_2O_{CW\ ONLY}$	= N_2O emissions from centralized wastewater treatment plants with constructed wetlands only (kt)
16		
17	$N_2O_{CW\ TERTIARY}$	= N_2O emissions from centralized wastewater treatment plants with constructed wetlands used as tertiary treatment (kt)
18		
19	$N_2O_{EFFLUENT}$	= N_2O emissions from wastewater effluent discharged to aquatic environments (kt)
20	US_{POP}	= U.S. population
21	US_{POPND}	= U.S. population that is served by biological denitrification
22	US_{POPCW}	= U.S. population that is served by only constructed wetland systems
23	$WWTP$	= Fraction of population using WWTP (as opposed to septic systems)
24	$POTW_flow_CW$	= Wastewater flow to POTWs that use constructed wetlands as tertiary treatment (MGD)
25		
26	EF_1	= Emission factor – plants without intentional nitrification or denitrification
27	EF_2	= Emission factor – plant with intentional denitrification
28	Protein	= Annual per capita protein consumption (kg/person/year)
29	$N_{CW,INF}$	= Influent nitrogen concentration to constructed wetlands used as tertiary treatment (mg/L)
30		
31	F_{NPR}	= Fraction of N in protein (kg N/kg protein)
32	$F_{NON-CON}$	= Factor for non-consumed protein added to wastewater
33	$F_{IND-COM}$	= Factor for industrial and commercial co-discharged protein into the sewer
34	N_{SLUDGE}	= N removed with sludge, kg N/yr
35	EF_3	= Emission factor (kg N_2O -N/kg sewage-N produced) – from effluent
36	EF_4	= Emission factor (kg N_2O -N/kg N produced) – constructed wetlands
37	3.79	= Conversion factor, liters to gallons
38	44/28	= Molecular weight ratio of N_2O to N_2
39	$1/10^6$	= Conversion factor, kg to Gg
40	$1/10^9$	= Conversion factor, g to Gg

41 U.S. population data were taken from the U.S. Census Bureau International Database (U.S. Census 2016) and
42 include the populations of the United States, American Samoa, Guam, Northern Mariana Islands, Puerto Rico, and
43 the Virgin Islands. The fraction of the U.S. population using wastewater treatment plants is based on data from the
44 1989, 1991, 1993, 1995, 1997, 1999, 2001, 2003, 2005, 2007, 2009, 2011, and 2013 *American Housing Survey*
45 (U.S. Census 2013). Data for intervening years were obtained by linear interpolation and data from 2014 and 2015
46 were forecasted using 1990 to 2013 and 1990 to 2014 data, respectively. The emission factor (EF_1) used to estimate
47 emissions from wastewater treatment for other plants was taken from IPCC (2006), while the emission factor (EF_2)
48 used to estimate emissions from wastewater treatment for plants with intentional denitrification was taken from
49 Scheehle and Doorn (2001). The emission factor (EF_4) used to estimate emissions from surface flow constructed
50 wetlands (0.0013 kg N_2O -N/kg N produced) was taken from IPCC (2014). Data on annual per capita protein intake
51 were provided by the U.S. Department of Agriculture Economic Research Service (USDA 2016b). Protein
52 consumption data for 2011 through 2015 were extrapolated from data for 1990 through 2010. An emission factor to

1 estimate emissions from effluent (EF₃) has not been specifically estimated for the United States, thus the default
 2 IPCC value (0.005 kg N₂O-N/kg sewage-N produced) was applied (IPCC 2006). The fraction of N in protein (0.16
 3 kg N/kg protein) was also obtained from IPCC (2006). The factor for non-consumed protein (1.2) and the factor for
 4 industrial and commercial co-discharged protein (1.25) were obtained from IPCC (2006). The amount of nitrogen
 5 removed by denitrification systems was taken from EPA (2008a), while the population served by denitrification
 6 systems was estimated from *Clean Watersheds Needs Survey* (EPA 1992, 1996, 2000, 2004, 2008b, and 2012).
 7 Sludge generation was obtained from EPA (1999) for 1988, 1996, and 1998 and from Beecher et al. (2007) for 2004.
 8 Intervening years were interpolated, and estimates for 2005 through 2015 were forecasted from the rest of the time
 9 series. The influent nitrogen concentration to constructed wetlands used as tertiary treatment (25 mg/L) was
 10 obtained from Metcalf & Eddy (2014). An estimate for the N removed as sludge (N_{SLUDGE}) was obtained by
 11 determining the amount of sludge disposed by incineration, by land application (agriculture or other), through
 12 surface disposal, in landfills, or through ocean dumping (EPA 1993b; Beecher et al. 2007; McFarland 2001; EPA
 13 1999). In 2015, 292 kt N was removed with sludge. Table 7-15 presents the data for U.S. population, population
 14 served by biological denitrification, population served by wastewater treatment plants, available protein, protein
 15 consumed, and nitrogen removed with sludge.

16 **Table 7-15: U.S. Population (Millions), Population Served by Biological Denitrification**

20 Uncertainty and Time-Series Consistency

21 The overall uncertainty associated with both the 2015 CH₄ and N₂O emission estimates from wastewater treatment
 22 and discharge was calculated using the *2006 IPCC Guidelines* Approach 2 methodology (IPCC 2006). Uncertainty
 23 associated with the parameters used to estimate CH₄ emissions include that of numerous input variables used to
 24 model emissions from domestic wastewater, and wastewater from pulp and paper manufacturing, meat and poultry
 25 processing, fruits and vegetable processing, ethanol production, and petroleum refining. Uncertainty associated with
 26 the parameters used to estimate N₂O emissions include that of sewage sludge disposal, total U.S. population,
 27 average protein consumed per person, fraction of N in protein, non-consumption nitrogen factor, emission factors
 28 per capita and per mass of sewage-N, and for the percentage of total population using centralized wastewater
 29 treatment plants. Uncertainty associated with constructed wetlands parameters including U.S. population served by
 30 constructed wetlands, and emission and conversion factors are from IPCC (2014), whereas uncertainty associated
 31 with POTW flow to constructed wetlands and influent BOD and nitrogen concentrations were based on expert
 32 judgment.

33 The results of this Approach 2 quantitative uncertainty analysis are summarized in Table 7-16. Methane emissions
 34 from wastewater treatment were estimated to be between 10.9 and 18.0 MMT CO₂ Eq. at the 95 percent confidence
 35 level (or in 19 out of 20 Monte Carlo Stochastic Simulations). This indicates a range of approximately 26 percent
 36 below to 22 percent above the 2015 emissions estimate of 14.8 MMT CO₂ Eq. Nitrous oxide emissions from
 37 wastewater treatment were estimated to be between 1.2 and 10.3 MMT CO₂ Eq., which indicates a range of
 38 approximately 75 percent below to 107 percent above the 2015 emissions estimate of 5.0 MMT CO₂ Eq.

Table 7-16: Approach 2 Quantitative Uncertainty Estimates for CH₄ Emissions from Wastewater Treatment (MMT CO₂ Eq. and Percent)

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate ^a			
			Lower Bound	Upper Bound	Lower Bound (%)	Upper Bound (%)
Wastewater Treatment	CH₄	14.8	10.9	18.0	-26%	+22%
Domestic	CH ₄	9.0	6.7	11.4	-25%	+27%
Industrial	CH ₄	5.8	3.0	8.3	-48%	+44%
Wastewater Treatment	N₂O	5.0	1.2	10.3	-75%	+107%

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time series to ensure time-series consistency from 1990 through 2015. Details on the emission trends through time are described in more detail in the Methodology section.

QA/QC and Verification

A QA/QC analysis was performed on activity data, documentation, and emission calculations. This effort included a Tier 1 analysis, including the following checks:

- Checked for transcription errors in data input;
- Ensured references were specified for all activity data used in the calculations;
- Checked a sample of each emission calculation used for the source category;
- Checked that parameter and emission units were correctly recorded and that appropriate conversion factors were used;
- Checked for temporal consistency in time series input data for each portion of the source category;
- Confirmed that estimates were calculated and reported for all portions of the source category and for all years;
- Investigated data gaps that affected emissions estimates trends; and
- Compared estimates to previous estimates to identify significant changes.

All transcription errors identified were corrected. The QA/QC analysis did not reveal any systemic inaccuracies or incorrect input values.

Recalculations Discussion

EPA concluded its investigation of constructed and semi-natural treatment wetlands and incorporated emissions estimates from these wastewater treatment scenarios for both methane and nitrous oxide into the Inventory. Flow to constructed wetlands and constructed wetlands used as tertiary treatment were determined with data available from *Clean Watersheds Needs Survey* (EPA 1992, 1996, 2000, 2004, 2008b, and 2012). Emissions and conversion factors as well as methodology associated with constructed wetlands were taken from IPCC (2014). For CH₄ emissions, the BOD concentration entering constructed wetlands used as tertiary treatment for the United States was set equal to POTW secondary treatment standards (EPA 2013). For N₂O emissions, the nitrogen concentration entering constructed wetlands used as tertiary treatment for the United States was conservatively estimated to be 25 mg/L (Metcalf & Eddy 2014). The inclusion of estimates for emissions from constructed wetlands resulted in minimal changes to overall methane and nitrous emissions from domestic wastewater for the entire time series. In addition, an analysis of 2008 and 2012 CWNS provided updated values for both the population associated with facilities with denitrification processes and the total wastewater flow to POTWs (EPA 2008b and 2012). Data for intervening years were obtained by linear interpolation and the years 2013 through 2015 were forecasted from the rest of the time series. This changed resulted in updated values for both the population served by biological denitrification and total wastewater flow for 2005 through 2014.

The calculation of the amount of N₂O emitted from wastewater effluent was updated to properly back-calculate and subtract out nitrogen associated with N₂O emissions from centralized treatment plants.

1 **Planned Improvements**

2 Data collected under the EPA's Greenhouse Gas Reporting Program Subpart II, Industrial Wastewater Treatment
3 (GHGRP) is being investigated for use in improving the emission estimates for the industrial wastewater category.
4 Because reporting data from EPA's GHGRP are not available for all Inventory years, ensuring time series
5 consistency has been a priority. In addition, the representativeness of GHGRP reporters has been investigated to
6 determine if moving to a facility-level implementation of GHGRP data is warranted, or whether the GHGRP data
7 will allow update of activity data for certain industry sectors, such as use of biogas recovery systems or update of
8 waste characterization data. Since EPA's GHGRP only includes reporters that have met the reporting threshold, and
9 because it is not currently possible to review whether reporters represent the majority of U.S. production, GHGRP
10 data are not believed to be sufficiently representative to move toward facility-level estimates in the Inventory.
11 However, EPA's GHGRP data continues to be evaluated for improvements to activity data, and in verifying
12 methodologies currently in use in the Inventory to estimate emissions (ERG 2014a, 2016). In implementing any
13 improvements and integration of data from EPA's GHGRP, the latest guidance from IPCC will be followed.⁷

14 In addition, reports continue to be investigated which could inform potential updates to the Inventory based on
15 international research. The Global Water Research Coalition (GWRC 2011) report was previously evaluated, which
16 included results of studies from Australia, France, the Netherlands and the US. Since each dataset was taken from a
17 variety of wastewater treatment plant types using different methodologies and protocols, it was not representative
18 enough to include in the Inventory (ERG 2014b). In addition to this report, wastewater inventory submissions from
19 other countries have been evaluated to determine if there are any emission factors, specific methodologies, or
20 additional industries that could be used to inform the U.S. inventory calculations. Although no comparable data have
21 been found, investigations into other countries' Inventory reports continues for investigating potential improvements
22 to the Inventory.

23 Currently, for domestic wastewater, it is assumed that all aerobic wastewater treatment systems are well-managed
24 and produce no CH₄ and that all anaerobic systems have an MCF of 0.8. Efforts to obtain better data reflecting
25 emissions from various types of municipal treatment systems are currently being pursued by researchers, including
26 the Water Environment Research Federation (WERF). This research includes data on emissions from partially
27 anaerobic treatment systems which have been reviewed, but the emissions were too variable and the sample size too
28 small to include in the Inventory at this time (Willis et al. 2013). In addition, information on flare efficiencies were
29 reviewed, but they were not suitable for use in updating the Inventory because the flares used in the study are likely
30 not comparable to those used at wastewater treatment plants (ERG 2014b). The status of this and similar research
31 continues to be monitored for potential inclusion in the Inventory in the future.

32 For industrial wastewater emissions, we are working with the National Council of Air and Stream Improvement
33 (NCASI) to determine if there are sufficient data available to update the estimates of organic loading in pulp and
34 paper wastewaters treated on site. These data include the estimates of wastewater generated per unit of production,
35 the BOD and/or COD concentration of these wastewaters, and the industry-level production basis used in the
36 Inventory. Data on the industry-level production basis to date has been received and will be incorporated, but in
37 order to incorporate that data, the production basis in relation to the wastewater generation rate and the organic
38 content of the wastewater needs to be evaluated to ensure it is incorporated correctly into the Inventory.

39 Breweries are also being evaluated as sources of industrial wastewater emissions to determine the scale of methane
40 quantities produced. A benchmarking study will be available in the near future which could improve preliminary
41 brewery estimates and fill in current data gaps for potential inclusion in future inventories.

42 The inclusion of wastewater treatment emissions from dairy products processing into Inventory estimates is being
43 investigated, and will continue focusing on contacts in industry groups, such as the National Milk Producers
44 Federation, to determine if there are readily available data on a national scale that could facilitate calculation of
45 national emission estimates from this industry.

46 The methodology to estimate CH₄ emissions from domestic wastewater treatment currently utilizes estimates for the
47 percentage of centrally treated wastewater that is treated by aerobic systems and anaerobic systems. These data

⁷ IPCC guidance for models and facility-level data, see <http://www.ipcc-nggip.iges.or.jp/public/tb/TFI_Technical_Bulletin_1.pdf>.

1 come from the 1992, 1996, 2000, and 2004 CWNS. The question of whether activity data for wastewater treatment
2 systems are sufficient across the time series to further differentiate aerobic systems with the potential to generate
3 small amounts of CH₄ (aerobic lagoons) versus other types of aerobic systems, and to differentiate between
4 anaerobic systems to allow for the use of different MCFs for different types of anaerobic treatment systems,
5 continues to be explored. A methodology was developed to use the 2008 and 2012 CWNS data for wastewater
6 treated in denitrification systems, and in future years of the Inventory it may be possible to utilize these years of the
7 CWNS to update the aerobic/anaerobic data. Additional information and other data continue to be evaluated to
8 update future years of the Inventory, including anaerobic digester data compiled by the North East Biosolids and
9 Residuals Association (NEBRA) in collaboration with several other entities. While NEBRA is no longer involved in
10 the project, the Water Environment Federation (WEF) now hosts and manages the dataset which has been relocated
11 to www.wef.org/biosolids. *Water Environment Federation (WEF) biosolid data continues to be evaluated as a*
12 *potential source of digester, sludge, and biogas data from POTWs.*

13 Previously, new measurement data from WERF were used to develop a U.S.-specific emission factor for CH₄
14 emissions from septic systems and incorporated into the Inventory emissions calculation. Due to the high
15 uncertainty of the measurements for N₂O from septic systems, estimates of N₂O emissions were not included.
16 Appropriate emission factors for septic system N₂O emissions will continue to be investigated as the data collected
17 by WERF indicate that septic systems are a source of N₂O emissions.

18 In addition, the estimate of N entering municipal treatment systems is under review. The factor that accounts for
19 non-sewage N in wastewater (bath, laundry, kitchen, industrial components) has a high uncertainty. Obtaining data
20 on the changes in average influent N concentrations to centralized treatment systems over the time series would
21 improve the estimate of total N entering the system, which would reduce or eliminate the need for other factors for
22 non-consumed protein or industrial flow. The dataset previously provided by the National Association of Clean
23 Water Agencies (NACWA) was reviewed to determine if it was representative of the larger population of
24 centralized treatment plants for potential inclusion into the Inventory. However, this limited dataset was not
25 representative of the number of systems by state or the service populations served in the United States, and therefore
26 could not be incorporated into the Inventory methodology. Additional data sources will continue to be researched
27 with the goal of improving the uncertainty of the estimate of N entering municipal treatment systems. Unfortunately,
28 NACWA's suggestion of using National Pollution Discharge Elimination System (NPDES) permit data to estimate
29 nitrogen loading rates is not feasible. Not every POTW is required to measure for N so the database is not a
30 complete source. Typically, only those POTWs that are required to reduce nutrients would be monitored, so the
31 database may reflect lower N effluent loadings than that typical throughout the United States.

32 Sources of data for development of a country-specific methodology for N₂O emissions associated with on-site
33 industrial wastewater treatment operations continue to be investigated, including the appropriateness of using
34 IPCC's default factor for domestic wastewater (0.005 kg N₂O-N/kg N).

35 The value used for N content of sludge also continues to be investigated. This value is driving the N₂O emissions for
36 wastewater treatment and is static over the time series. To date, new data have not been identified that would be able
37 to establish a time series for this value. The amount of sludge produced and sludge disposal practices will also be
38 investigated. In addition, based on UNFCCC review comments, the transparency of the fate of sludge produced in
39 wastewater treatment will continue to be improved.

40 7.3 Composting (IPCC Source Category 5B1)

41 Composting of organic waste, such as food waste, garden (yard) and park waste, and wastewater treatment sludge
42 and/or biosolids, is common in the United States. Advantages of composting include reduced volume of the waste,
43 stabilization of the waste, and destruction of pathogens in the waste. The end products of composting, depending on
44 its quality, can be recycled as a fertilizer and soil amendment, or be disposed of in a landfill.

45 Composting is an aerobic process and a large fraction of the degradable organic carbon in the waste material is
46 converted into carbon dioxide (CO₂). Methane (CH₄) is formed in anaerobic sections of the compost, which are
47 created when there is excessive moisture or inadequate aeration (or mixing) of the compost pile. This CH₄ is then
48 oxidized to a large extent in the aerobic sections of the compost. The estimated CH₄ released into the atmosphere
49 ranges from less than 1 percent to a few percent of the initial C content in the material (IPCC 2006). Depending on

1 how well the compost pile is managed, nitrous oxide (N₂O) emissions can be produced. The formation of N₂O
 2 depends on the initial nitrogen content of the material and is mostly due to nitrogen oxide (NO_x) denitrification
 3 during the later composting stages. Emissions vary and range from less than 0.5 percent to 5 percent of the initial
 4 nitrogen content of the material (IPCC 2006). Animal manures are typically expected to generate more N₂O than, for
 5 example, yard waste, however data are limited.

6 From 1990 to 2015, the amount of waste composted in the United States has increased from 3,810 kt to 21,052 kt.
 7 The amount composted in 2015 is at an all-time high for the Inventory time series (see Table 7-19). Over the past
 8 decade, the amount of waste composted has fluctuated. A peak of 20,049 kt composted was observed in 2008,
 9 followed by a steep drop the following year to 18,824 kt composted, presumably driven by the economic crisis.
 10 Since then, the amount of waste composted has gradually increased, and when comparing 2009 to 2015, a 12 percent
 11 increase in waste composted is observed. Emissions of CH₄ and N₂O from composting from 2009 to 2015 have
 12 increased by the same percentage. In 2015, CH₄ emissions from composting (see Table 7-17 and Table 7-18) were
 13 2.1 MMT CO₂ Eq. (84.2 kt), and N₂O emissions from composting were 1.9 MMT CO₂ Eq. (6.3 kt). The wastes
 14 composted primarily include yard trimmings (grass, leaves, and tree and brush trimmings) and food scraps from the
 15 residential and commercial sectors (such as grocery stores; restaurants; and school, business, and factory cafeterias).
 16 The composted waste quantities reported here do not include backyard composting or agricultural composting.

17 The growth in composting since the 1990s and specifically over the past decade is attributable primarily to three
 18 factors: (1) the enactment of legislation by state and local governments that discouraged the disposal of yard
 19 trimmings in landfills, (2) yard trimming collection and yard trimming drop off sites provided by local solid waste
 20 management districts/divisions, and (3) an increased awareness of the environmental benefits of composting. Most
 21 bans on the disposal of yard trimmings were initiated in the early 1990's by state or local governments (US
 22 Composting Council 2010). By 2010, 25 states, representing about 50 percent of the nation's population, had
 23 enacted such legislation (BioCycle 2010). An additional 16 states are known to have commercial-scale composting
 24 facilities (Shin 2014). In the past 5 years, the amount of waste composted has gradually increased from 20.2 million
 25 tons in 2010 to 23.2 million tons in 2015 (see Table 7-19).

26 **Table 7-17: CH₄ and N₂O Emissions from Composting (MMT CO₂ Eq.)**

Activity	1990	2005	2011	2012	2013	2014	2015
CH ₄	0.4	1.9	1.9	1.9	2.0	2.1	2.1
N ₂ O	0.3	1.7	1.7	1.7	1.8	1.9	1.9
Total	0.7	3.6	3.5	3.7	3.9	4.0	4.0

27

28 **Table 7-18: CH₄ and N₂O Emissions from Composting (kt)**

Activity	1990	2005	2011	2012	2013	2014	2015
CH ₄	15.2	74.6	74.6	77.4	81.4	83.5	84.2
N ₂ O	1.1	5.6	5.6	5.8	6.1	6.3	6.3

29 Methodology

30 Methane and N₂O emissions from composting depend on factors such as the type of waste composted, the amount
 31 and type of supporting material (such as wood chips and peat) used, temperature, moisture content (e.g., wet and
 32 fluid versus dry and crumbly), and aeration during the composting process.

33 The emissions shown in Table 7-17 and Table 7-18 were estimated using the IPCC default (Tier 1) methodology
 34 (IPCC 2006), which is the product of an emission factor and the mass of organic waste composted (note: no CH₄
 35 recovery is expected to occur at composting operations in the emission estimates presented):

36

37 where,

38 E_i = CH₄ or N₂O emissions from composting, kt CH₄ or N₂O,
 39 M = mass of organic waste composted in kt,

$$E_i = M \times EF_i$$

1 EF_i = emission factor for composting, 4 t CH₄/kt of waste treated (wet basis) and 0.3
 2 t N₂O/kt of waste treated (wet basis) (IPCC 2006), and
 3 i = designates either CH₄ or N₂O.

4 Estimates of the quantity of waste composted (M) are presented in Table 7-19 for select years. Estimates of the
 5 quantity composted for 1990, 2005, 2010, and 2012 to 2014 were taken from EPA’s *Advancing Sustainable*
 6 *Materials Management: Facts and Figures 2014* (EPA 2016); the estimate of the quantity composted for 2011 was
 7 taken from EPA’s *Municipal Solid Waste In The United States: 2012 Facts and Figures* (EPA 2014); estimates of
 8 the quantity composted for 2015 were extrapolated using the 2014 quantity composted and a ratio of the U.S.
 9 population growth between 2014 and 2015 (U.S. Census Bureau 2016).

10 **Table 7-19: U.S. Waste Composted (kt)**

Activity	1990	2005	2011	2012	2013	2014	2015
Waste Composted	3,810	18,643	18,661	19,351	20,358	20,884	21,052

11 Uncertainty and Time-Series Consistency

12 The estimated uncertainty from the 2006 IPCC Guidelines is ±50 percent for the Approach 1 methodology.
 13 Emissions from composting in 2015 were estimated to be between 2.0 and 6.0 MMT CO₂ Eq., which indicates a
 14 range of 50 percent below to 50 percent above the actual 2015 emission estimate of 4.0 MMT CO₂ Eq. (see Table
 15 7-20).

16 **Table 7-20: Approach 1 Quantitative Uncertainty Estimates for Emissions from Composting**
 17 **(MMT CO₂ Eq. and Percent)**

Source	Gas	2015 Emission Estimate (MMT CO ₂ Eq.)	Uncertainty Range Relative to Emission Estimate (%)			
			Lower Bound	Upper Bound	Lower Bound	Upper Bound
Composting	CH ₄ , N ₂ O	4.0	2.0	6.0	-50%	+50%

18 QA/QC and Verification

19 A QA/QC analysis was performed for data gathering and input, documentation, and calculation. A primary focus of
 20 the QA/QC checks was to ensure that the amount of waste composted annually was correct according to the latest
 21 EPA *Advancing Sustainable Materials Management: Facts and Figures* report.

22 Recalculations Discussion

23 No recalculations were made in this Inventory year.

24 Planned Improvements

25 For future Inventories, additional efforts will be made to improve the estimates of CH₄ and N₂O emissions from
 26 composting. For example, a literature search on emission factors and composting systems and management
 27 techniques has been completed and will be documented for the next Inventory year. The purpose of this literature
 28 review was to compile all published emission factors specific to various composting systems and composted
 29 materials. This information will be used to determine whether the emission factors used in the current methodology
 30 should be revised, or expanded to account for geographical differences and/or differences in composting systems
 31 used. For example, outdoor composting processes in arid regions typically require the addition of moisture
 32 compared to similar composting processes in wetter climates. Additionally, composting systems that primarily
 33 compost food waste may generate CH₄ at different rates than those that compost yard trimmings because the food

1 waste may have a higher moisture content and more readily degradable material. Further cooperation with
 2 estimating emissions in cooperation with the LULUCF Other section will also be investigated.

3 7.4 Waste Incineration (IPCC Source Category 4 5C1)

5 As stated earlier in this chapter, carbon dioxide (CO₂), nitrous oxide (N₂O), and methane (CH₄) emissions from the
 6 incineration of waste are accounted for in the Energy sector rather than in the Waste sector because almost all
 7 incineration of municipal solid waste (MSW) in the United States occurs at waste-to-energy facilities where useful
 8 energy is recovered. Similarly, the Energy sector also includes an estimate of emissions from burning waste tires and
 9 hazardous industrial waste, because virtually all of the combustion occurs in industrial and utility boilers that
 10 recover energy. The incineration of waste in the United States in 2015 resulted in 11.0 MMT CO₂ Eq., over half of
 11 which (5.9 MMT CO₂ Eq.) is attributable to the combustion of plastics. For more details on emissions from the
 12 incineration of waste, see Section 3.3 of the Energy chapter.

13 Additional sources of emissions from waste incineration include non-hazardous industrial waste incineration and
 14 medical waste incineration. As described in Annex 5 of this report, data are not readily available for these sources
 15 and emission estimates are not provided. An analysis of the likely level of emissions was conducted based on a 2009
 16 study of hospital/ medical/ infectious waste incinerator (HMIWI) facilities in the United States (RTI 2009). Based
 17 on that study's information of waste throughput and an analysis of the fossil-based composition of the waste, it was
 18 determined that annual greenhouse gas emissions for medical waste incineration would be below 500 kt CO₂ Eq. per
 19 year and considered insignificant for the purposes of Inventory reporting under the UNFCCC. More information on
 20 this analysis is provided in Annex 5.

21 7.5 Waste Sources of Indirect Greenhouse 22 Gases

23 In addition to the main greenhouse gases addressed above, waste generating and handling processes are also sources
 24 of indirect greenhouse gas emissions. Total emissions of nitrogen oxides (NO_x), carbon monoxide (CO), and non-
 25 CH₄ volatile organic compounds (NMVOCs) from waste sources for the years 1990 through 2015 are provided in
 26 Table 7-21.

27 **Table 7-21: Emissions of NO_x, CO, and NMVOC from Waste (kt)**

Gas/Source	1990	2005	2011	2012	2013	2014	2015

Miscellaneous ^a	557	43	15	17	19	22	22
Landfills	58	22	7	8	10	11	11

+ Does not exceed 0.5 kt.

^a Miscellaneous includes TSDFs (Treatment, Storage, and Disposal Facilities under the Resource Conservation and Recovery Act [42 U.S.C. § 6924, SWDA § 3004]) and other waste categories.
Note: Totals may not sum due to independent rounding.

1 **Methodology**

2 Emission estimates for 1990 through 2015 were obtained from data published on the National Emission Inventory
3 (NEI) Air Pollutant Emission Trends web site (EPA 2016), and disaggregated based on EPA (2003). Emission
4 estimates for 2012 and 2013 for non-electric generating units (EGU) are held constant from 2011 in EPA (2016).
5 Emission estimates for 2012 and 2013 for non-mobile sources are recalculated emissions by interpolation from 2015
6 in EPA (2016). Emission estimates of these gases were provided by sector, using a “top down” estimating
7 procedure—emissions were calculated either for individual sources or for many sources combined, using basic
8 activity data (e.g., the amount of raw material processed) as an indicator of emissions. National activity data were
9 collected for individual categories from various agencies. Depending on the category, these basic activity data may
10 include data on production, fuel deliveries, raw material processed, etc.

11 **Uncertainty and Time-Series Consistency**

12 No quantitative estimates of uncertainty were calculated for this source category. Methodological recalculations
13 were applied to the entire time-series to ensure time-series consistency from 1990 through 2015. Details on the
14 emission trends through time are described in more detail in the Methodology section, above.

1 **8. Other**

2 The United States does not report any greenhouse gas emissions under the Intergovernmental Panel on Climate
3 Change (IPCC) “Other” sector.

4

9. Recalculations and Improvements

Each year, emission and sink estimates are recalculated and revised for all years in the *Inventory of U.S. Greenhouse Gas Emissions and Sinks*, as attempts are made to improve both the analyses themselves, through the use of better methods or data, and the overall usefulness of the report. In this effort, the United States follows the *2006 IPCC Guidelines* (IPCC 2006), which states, “Both methodological changes and refinements over time are an essential part of improving inventory quality. It is *good practice* to change or refine methods when available data have changed; the previously used method is not consistent with the IPCC guidelines for that category; a category has become key; the previously used method is insufficient to reflect mitigation activities in a transparent manner; the capacity for inventory preparation has increased; new inventory methods become available; and for correction of errors.”

The results of all methodological changes and historical data updates made in the current Inventory report are presented in this section; detailed descriptions of each recalculation are contained within each source’s description found in this report, if applicable. Table 9-1 summarizes the quantitative effect of these changes on U.S. greenhouse gas emissions and sinks and Table 9-2 summarizes the quantitative effect on annual net CO₂ fluxes, both relative to the previously published U.S. Inventory (i.e., the 1990 through 2015 report). These tables present the magnitude of these changes in units of million metric tons of carbon dioxide equivalent (MMT CO₂ Eq.).

The Recalculations Discussion section of each source’s description in the respective chapter of this Inventory presents the details of each recalculation. In general, when methodological changes have been implemented, the entire time series (i.e., 1990 through 2015) has been recalculated to reflect the change, per IPCC (2006). Changes in historical data are generally the result of changes in statistical data supplied by other agencies.

The following ten emission sources and sinks underwent some of the most significant methodological and historical data changes. These emission sources consider only methodological and historical data changes. A brief summary of the recalculations and/or improvements undertaken is provided for each of the ten sources.

- *Land Converted to Grassland - Changes in Agricultural Soil Carbon Stocks (CO₂)*. Methodological recalculations in the current Inventory are associated with the following improvements, including: (1) driving the DAYCENT simulations with updated input data for land use and management from the National Resources Inventory extending the time series through 2012; (2) modifying the number of experimental study sites used to quantify model uncertainty; (3) DAYCENT model development to improve the simulation of soil temperature; (4) improvements in the cropping and land use histories that are simulated in DAYCENT between 1950 and 1979 that generate initial values for the model state variables, including the initial soil organic C stock values; and (5) incorporating belowground biomass, dead wood and litter C stock losses for *Forest Land Converted to Grassland*. As a result of these improvements to the Inventory, changes in stocks declined, relative to the previous report, by an average of 272.9 MMT CO₂ Eq. annually over the time series. This represents a 673 percent increase in the losses of carbon from *Land Converted to Grassland* compared to the previous Inventory. This change is due to a larger amount of aboveground biomass C that is lost from *Forest Land Converted to Grasslands*, in addition to inclusion of belowground biomass, dead wood and litter C stock changes in this Inventory.
- *Land Converted to Forest Land* - This is the second U.S. Inventory report to include a *Land Converted to Forest Land* section containing specific soil C stock change estimates and the first Inventory report to include all C pools for *Land Converted to Forest Land*. In prior Inventory reports (e.g., EPA 2015), the C stock changes from *Land Converted to Forest Land* were a part of the *Forest Land Remaining Forest Land* estimates. See the

1 Recalculations section in *Forest Land Remaining Forest Land* for a detailed explanation on overall changes
2 resulting from implementing a different methodological approach in the current Inventory report. These
3 changes, particularly the inclusion of biomass, dead wood and litter in the estimates resulted in an average
4 annual increase in sequestration of 89.9 MMT CO₂ Eq. relative to the previous Inventory.

- 5 • *Agricultural Soil Management (N₂O)*. Methodological recalculations in the current Inventory are associated
6 with the following improvements: (1) driving the DAYCENT simulations with updated input data for land
7 management from the National Resources Inventory extending the time series through 2012; (2) modifying the
8 number of experimental study sites used to quantify model uncertainty for direct N₂O emissions; (3)
9 DAYCENT model development to improve the simulation of soil temperature; (4) improvements in the
10 cropping and land use histories that are simulated in DAYCENT between 1950 and 1979 that generate initial
11 values for the model state variables, such as initial soil organic C stock values; and (5) implementing a more
12 robust set of model output variables that enabled a more accurate and detailed accounting of N from synthetic
13 fertilizers, managed manure, and PRP manure applied to grasslands. These changes resulted in a decrease in
14 emissions of approximately 14.4 percent on average relative to the previous Inventory and an increase in the
15 upper bound of the 95 percent confidence interval for direct N₂O emissions from 24 to 31 percent. The
16 differences in emissions and uncertainty are mainly due to increasing the number of study sites used to quantify
17 model uncertainty. These changes resulted in an average annual increase in emissions of 44.5 MMT CO₂ Eq.
18 relative to the previous Inventory.
- 19 • *Forest Land Remaining Forest Land - Changes in Forest Carbon Stock (CO₂ sink)*. Forest ecosystem stock and
20 stock-change estimates differ from previous Inventory reports in two primary ways. First, a different estimation
21 system was used in this Inventory and the 1990-2014 report (Woodall et al. 2015a). The major differences
22 between the estimation system used in the last two Inventory reports and past estimation approaches is the sole
23 use of annual FIA data and the back-casting of forest C stocks across the 1990s based on forest C stock density
24 and land use change information obtained from the nationally consistent annual forest inventory coupled with in
25 situ observations of non-tree C pools such as soils, dead wood, and litter in the 1990-2014 Inventory and this
26 Inventory. The use of this estimation framework has enabled the creation of the two land use sections for forest
27 C stocks: *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*. In prior Inventory reports
28 (e.g., the 1990-2013 Inventory), the C stock changes from *Land Converted to Forest Land* were a part of the
29 *Forest Land Remaining Forest Land* section and it was not possible to disaggregate the estimates with the
30 methodology applied at that time. A second major change in the 1990-2014 Inventory submission was the
31 adoption of a new approach to estimate forest soil C, the largest C stock in the United States. However, the litter
32 and soil C stock and stock change estimates reported in the 1990-2014 Inventory were inadvertently compiled
33 using English units resulting in estimates that were 2.2 times larger than they should have been for the *Forest*
34 *Land Remaining Forest Land* category. This mistake was not caught during compilation of the previous
35 Inventory report since the soil C model and the estimation system used to compile estimates for the United
36 States were both being used for the first time with no similar (e.g., national-level population estimates using
37 similar data) estimates available for comparison. In addition to these major changes, the refined land
38 representation analysis described in Section 6.1 *Representation of the U.S. Land Base* re-classified some of the
39 forest land in south central and southeastern coastal Alaska as unmanaged; this is in contrast to past
40 assumptions where forest lands included in the FIA database were always considered part of the “managed”
41 land base. Therefore, the C stock and flux estimates for southeast and south central coastal Alaska, as included
42 here, reflect that adjustment, which effectively reduces the managed forest area by approximately 5 percent.

43
44 In addition to the creation of explicit estimates of removals and emissions from *Forest Land Remaining Forest*
45 *Land* and *Land Converted to Forest Land*, the estimation system used in the current Inventory and the 1990-
46 2014 Inventory eliminated the use of periodic data (which may be inconsistent with annual inventory data) and
47 contributed to a data artifact in prior estimates of emissions/removals from 1990 to the present. In the previous
48 Inventory reports (i.e., prior to the 1990-2014 Inventory), there was a reduction in net sequestration from 1995
49 to 2000 followed by an increase in net sequestration from 2000 to 2004. This artifact, resulting from comparing
50 inconsistent inventories of the 1980s through 1990s to the nationally consistent inventories of the 2000s has
51 been removed in the last two Inventory reports. All these changes resulted in an average annual increase in
52 sequestration of 39.9 MMT CO₂ Eq. relative to the previous Inventory.

- 53 • *Land Converted to Cropland - Changes in Agricultural Carbon Stocks (CO₂)*. Methodological recalculations in
54 the current Inventory are associated with the following improvements: (1) driving the DAYCENT simulations

1 with updated input data for land use and management from the National Resources Inventory extending the time
2 series through 2012; (2) modifying the number of experimental study sites used to quantify model uncertainty;
3 (3) DAYCENT model development to improve the simulation of soil temperature; (4) improvements in the
4 cropping and land use histories that are simulated in DAYCENT between 1950 and 1979 that generate initial
5 values for the model state variables, including the initial soil organic C stock values; and (5) incorporating
6 belowground biomass, dead wood and litter C stock losses with *Forest Land Converted to Cropland*. As a result
7 of these improvements to the Inventory, *Land Converted to Cropland* have a larger reported loss of C, estimated
8 at 19.1 MMT CO₂ Eq. over the time series. This represents a 45 percent increase in the losses of carbon with
9 *Land Converted to Cropland* compared to the previous Inventory, and is largely driven by reporting
10 belowground biomass, dead wood and litter C loss from *Forest Land Converted to Croplands*.

- 11 • *Natural Gas Systems (CH₄)*. EPA received information and data related to the emission estimates through the
12 Inventory preparation process, previous Inventories' formal public notice periods, GHGRP data, and new
13 studies. EPA carefully evaluated relevant information available, and made several updates to this review draft,
14 including revisions to production segment activity and emissions data, gathering and boosting facility
15 emissions, and processing segment activity and emissions data. In January 2017, EPA released draft memos that
16 discussed the changes under consideration and requested stakeholder feedback on those changes. In this public
17 review draft of the 1990-2015 Inventory, EPA has selected from the options presented in the 2017 Production
18 and Processing memos to develop emission estimates. The impact of all revisions to natural gas systems is an
19 average annual decrease in emissions of 15.3 MMT CO₂ Eq. relative to the previous Inventory.
- 20 • *Landfills (CH₄)*. Four major methodological recalculations were performed for the current Inventory. First, net
21 CH₄ emissions as directly reported to subpart HH of EPA's GHGRP were used for 2010 to 2015. Second, a 12.5
22 percent scale up factor was applied to the subpart HH data to account for emissions from MSW landfills that are
23 not required to report under subpart HH. Third, the net CH₄ emissions from 2010 to 2015 from subpart HH
24 were used to estimate, or back-cast, net CH₄ emissions for 2005 to 2009. Fourth, the previously used method,
25 which relies on the first order decay model, was applied with revised MSW generation data for years 1990 to
26 2004. The overall impact to the Inventory from these changes resulted in an average increase of nearly 7 percent
27 across the time series. These changes resulted in an average annual decrease in emissions of 10.2 MMT CO₂
28 Eq. relative to the previous Inventory.
- 29 • *Cropland Remaining Cropland - Changes in Agricultural Carbon Stocks (CO₂ sink)*. Methodological
30 recalculations in the current Inventory are associated with the following improvements: (1) driving the
31 DAYCENT simulations with updated input data for land management from the National Resources Inventory
32 from 1979 through 2012; (2) increasing the number of experimental study sites used to quantify model
33 uncertainty; (3) DAYCENT model development to improve the simulation of soil temperature; and (4)
34 improvements in the cropping and land use histories that are simulated in DAYCENT between 1950 and 1979
35 to reduce the amount of grassland converted into cropland when the NRI histories begin in 1979 (Note the
36 histories generate initial values for the model state variables, including the initial soil organic C stock values;
37 more detail is provide in Annex 3.12). These changes in SOC stocks resulted in an average annual decrease in
38 sequestration of 7.5 MMT CO₂ Eq. relative to the previous Inventory.
- 39 • *Petroleum Systems (CH₄)*. The EPA received information and data related to the emission estimates through the
40 Inventory preparation process, previous Inventories' formal public notice periods, EPA's Greenhouse Gas
41 Reporting Program (GHGRP) data, and new studies. The EPA carefully evaluated relevant information
42 available, and made revisions to the production segment methodology this public review draft of the Inventory
43 including revised well count, equipment count, and pneumatic controller activity data, and revised activity and
44 emissions data for tanks and associated gas venting and flaring. While the recalculations resulted in a decrease
45 in calculated emissions in recent years (e.g., a 35 percent decrease in the 2014 estimate), over the full time
46 series, the changes resulted in an average annual increase in emissions of 3.2 MMT CO₂ Eq. relative to the
47 previous Inventory. The recalculations resulted in increases in the emission estimate in early years of the time
48 series, primarily due to recalculations related to associated gas venting and flaring, and decreases in the
49 emission estimate in later years of the time series, primarily due to recalculations for pneumatic controllers.
- 50
51 • *Rice Cultivation (CH₄)*. Methodological recalculations in the current Inventory are associated with the following
52 improvements: (1) DAYCENT model development to improve the simulation of soil temperature; (2)
53 improvements in the cropping and land use histories that are simulated in DAYCENT between 1950 and 1979,

which generate initial values for the state variables in the model and (3) driving the DAYCENT simulations with updated input data for land use and management from the National Resources Inventory, which revised the time series from 1990 through 2012. These changes resulted in an increase in emissions of approximately 25 percent on average relative to the previous Inventory and an increase in uncertainty from confidence interval with a lower bound and upper bound of 17 percent to a confidence interval with an upper and lower bound of 28 percent. These changes resulted in an average annual increase in emissions of 2.9 MMT CO₂ Eq. relative to the previous Inventory.

Changes in Settlement Soil Carbon Stock	NC*	NC*	NC*	NC*	NC*	NC*	NC*
LULUCF Emissions^f	(3.5)	(4.2)	(2.2)	(5.6)	(4.2)	(4.2)	
Net Change in LULUCF C Stock Change^g	292.3	387.4	389.1	367.6	393.4	397.8	
LULUCF Sector Net Total^h	288.9	383.2	386.9	362.0	389.2	393.7	
Percent Change	39.1%	54.9%	50.8%	48.3%	51.2%	51.6%	

NC (No Change)

+ Absolute value does not exceed 0.05 MMT CO₂ Eq. or 0.05 percent.

* Indicates a new source for the current Inventory year.

^a Includes the effects of net additions to stocks of carbon stored in forest ecosystem pools and harvested wood products.

^b Estimates include emissions from N fertilizer additions on both *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*, but not from land-use conversion.

^c Estimates include C stock changes in all pools.

^d Quality control uncovered errors in the estimate and uncertainty of soil C stock changes for 2013, 2014, 2015, which will be updated following public review. Corrected estimates are provided in footnotes of the emission summary tables for *Cropland Remaining Cropland*, *Land Converted to Cropland*, *Grassland Remaining Grassland*, and *Land Converted to Grassland* sections in the LULUCF chapter of this report.

^e Estimates include emissions from N fertilizer additions on both *Settlements Remaining Settlements* and *Land Converted to Settlements*.

^f LULUCF emissions include the CO₂, CH₄, and N₂O emissions from *Peatlands Remaining Peatlands*; CH₄ and N₂O emissions reported for Non-CO₂ Emissions from Forest Fires, Non-CO₂ Emissions from Grassland Fires, and *Coastal Wetlands Remaining Coastal Wetlands*; CH₄ emissions from *Land Converted to Coastal Wetlands*; and N₂O Fluxes from Forest Soils and Settlement Soils.

^g LULUCF C Stock Change includes any C stock gains and losses from all land use and land use conversion categories.

^h The LULUCF Sector Net Total is the net sum of all emissions (i.e., sources) of greenhouse gases to the atmosphere plus removals of CO₂ (i.e., sinks or negative emissions) from the atmosphere.

Notes: Numbers in parentheses indicate an increase in C sequestration. Totals may not sum due to independent rounding.
